### INTRODUCTION

The Air Force Office of Scientific Research Technical Report Summaries are published quarterly as of March, June, September, and December of each calendar year. They consist of a brief summary of each AFOSR technical report received in the Technical Information Division and submitted to the Defense Technical Information Center (DTIC) for that quarter. The summaries contain two indexes for easily locating the technical reports that may be of interest to the user. These are followed by abstracts of the reports.

#### 1) SUBJECT INDEX

- a. Subject Field
- b. Title of Report
- c. AD Number (Accession Number)

#### 2) PERSONAL AUTHOR INDEX

- a. Primary Author
- b. Title of Report
- c. AD Number

AFOSR does not maintain copies of technical reports for distribution. However, you may obtain any of these reports if you are a registered government agency or government contractor with DTIC, by requesting the AD number of that report from the DTIC, Cameron Station, Alexandria, Virginia, 22314.

### PURPOSE

The purpose of this report is to inform Air Force Laboratories about the science that the Air Force Office of Scientific Research is supporting.

### AFOSR MISSION

The Air Force Office of Scientific Research (AFOSR) is the Single Manager of the Air Force Defense Research Sciences Program (Program Element 61102F) and the primary Air Force agency for the extramural support of fundamental scientific research. The AFOSR is organizationally under the DCS/Science and Technology, Air Force Systems Command.

AFOSR awards grants and contracts for research in areas of science relevant to the needs of the Air Force. Research is selected for support from proposals received in response to the Broad Agency Announcement originating from scientists investigating problems involving the search for new knowledge and the expansion of scientific principles. Selection is on the basis of scientific potential for improving Air Force operational capabilities, originality, significance to science, the qualification of the principal investigators, and the reasonableness of the proposed budget.

## KEY TO READING THE DATA

The summaries consist of two indexes and the abstracts. From one of the two indexes, locate the AD number of the report that is of interest to you. Use this number to locate the abstract of the report in the abstracts section. The first report submitted to DTIC during the quarter (the one with the lowest AD number) appears on the last page of the abstracts section. The last report submitted to DTIC during the quarter (the one with the highest DTIC number) appears on the first page of the abstracts section. The following terms will give you a brief description of the elements used in each summary of this report.

**DTIC Report Bibliography** - DTIC's brief description of a technical report.

**Search Control Number** - A number assigned by DTIC at the time a bibliography is printed.

**AD Number** - A number assigned to each technical report when received by the DTIC.

**Field & Group Numbers** - (appearing after the AD number) First number is the subject field and the second number after the slash is the particular group under that subject field.

**Corporate Author/Performing Organization** - The organization; e.g., college/university, company, etc., at which the research is conducted.

**Title** - The title of the technical report.

**Descriptive Note** - Gives the type of report; e.g., final, interim, etc., and the period of the time of the research.

**Date** - Date of the technical report.

**Pages** - Total number of pages contained in the technical report.

**Personal Author** - Person or persons who wrote the report.

**Contract/Grant Number** - The instrument control number identifying the contracting activity and funding year under which the research is initiated.

**Project Number** - A number unique to a particular area of science; e.g., 2304 is the project number for mathematics.

**Task Number** - An alphanumeric number unique to a specific field of the main area of science; e.g., 2304 is the project number for mathematics and A3 is the task number for computational sciences.

**Monitor Number** - The number assigned to a particular report by the government agency monitoring the research. The number consists of the government monitor acronym, the present calendar year and the technical report assigned consecutively; e.g., AFOSR-TR-83-0001 is the first number used for the first technical report processed for Calendar Year 1983.

**Supplementary Note** - A variety of statements pertaining to a report. For example, if the report is a journal article, the supplementary note might give you the journal citation, which will include the name of the journal the article it appears in, and the volume number, date, and the page numbers of the journal.

**Abstract** - A brief summary describing the research of the report.

**Descriptors** - Key words describing the research.

**Identifiers** - Commonly used designators, such as names of equipment, names of projects or acronyms, the AFOSR project and task number, and the Air Force Research Program Element number.

ABSTRACT: (U) This report documents Short Wavelength Chemical Laser (SWCL) activities performed for the Air Force Office of Scientific Research (AFOSR) and the Strategic Defense Initiative Organization (SDIO). These included the organization and planning of a SWCL workshop, comparative analysis of the chemical HF and oxygen/iodine lasers for specific applications, quantification of the critical kinetic pathways in the NF-IF transfer chemical laser and evaluation of novel SWCL concepts.

ABSTRACT: (U) The mechanical force sensing approach to low energy neutrino detection acquired an even greater emphasis because of the strong interest expressed by DARPA in performing a rigorous verification of Prof. Weber's claim that he has detected, at the U. of Maryland, low-energy antineutrinos, radiated by a 800 Curie tritium source, by using a room temperature torsion-balance. The engineering definition is made of a cryogenic force sensor that is expected to improve by several orders of magnitude on Prof. Weber torsion-balance's sensitivity. An area of concentration will be to identify causes, other than neutrino-induced effects, of the signal that might appear at the output of the sensors used in the tests. Some examples follow herewith. Several safeguards are planned concerning the isolation of the cryogenic force sensor against vibrations and acoustical oscillations. One is to construct the 4 k cryostat with an inner chamber evacuated of air. It is inside this chamber that the gravimetry gradiometer is installed.

hanging like a pendulum from a suspension at the top of the cryostat. The resonance frequency of the suspension will be as low as feasible, 0.1 Hz or lower, and provisions will be made to have the frequency of the signal as high as possible, possibly 100 Hz, by mechanically rotating the source. This way, the sensor will achieve a substantial attenuation of floor vibrations at the frequency of interest.

Distribution limited to DoD and DoD contractors only; Critical Technology; Sep 86. Other requests must be referred to Air Force Systems Command, AFMIL/POPR, Wright-Patterson AFB, OH 45433.

ABSTRACT: (U) An analysis model of the formation of liquid boron oxide from B2O3 gas and various gaseous H2O species (monomer, dimer, trimer) during expansion of a boron-loaded combustion product stream through a converging-diverging nozzle has been developed. Finite gas reaction kinetics, homogeneous nucleation, and deposition of gas molecules on homogeneous nuclei and heterogeneous seed particles (e.g. MgO) for subsequent particle growth are treated. Several options for growth processes are examined. It is concluded that use of simple collision theory (collisions of gas molecules with droplets yielding condensation) without consideration of thermal accommodation effects (balancing of heat transfer rate from the droplets to the gas in which they are entrained against rate of deposition of latent heat into the droplets from condensation of gaseous molecules on them) leads to non-negligible errors in predicted condensation rates (overly high rates being predicted). Parametric studies indicate that use of seed particles at

ABSTRACT: (U) The tensile stress-strain behavior of a series of discontinuously reinforced aluminum alloy composites containing 0, 8, and 20 volume percent SiC was examined. Comparisons were made between the behavior of age-hardenable (2124) vs solution-hardened (5456) matrix alloys, whisker vs particulate forms of the SiC reinforcement, and various states of matrix precipitation. The elastic modulus and work-hardening rate of both matrix alloys increased systematically with the addition of SiC. In the solution-hardened alloy, the effects of whiskers were greater than those of particulate, while in the age-hardenable alloy, they were equivalent. In both alloys, the proportional limit of the 8% SiC composites was less than that of the unreinforced PM matrix. Increasing the SiC to 20% raised the proportional limit, but in 2124 the proportional limit of the 20% composites was still below that of the PM material. This reduction in proportional limit behavior was characteristic of all of the heat treatment conditions examined, with the

exception of the T8 temper, which showed a monotonic increase in the proportional limit with increased SiC content. This phenomenon is thought to be caused by the presence of mobile dislocations generated by the thermal expansion mismatch between SiC content. This phenomenon is thought to be caused by the presence of mobile dislocations generated by the thermal expansion mismatch between SiC and aluminum. The state of matrix precipitation was found to have a pronounced effect on the mechanical properties of the composite. The proportional limit of the 20% SiC/2124 composite varied from 8 ksi in the annealed condition to 95 ksi in the T8.

ABSTRACT: (U) A new approach for analyzing the performance of communication networks with unreliable components was given in a recent paper. An algorithm was developed to generate the most probable states of a network, and an analysis of those states gave a good approximation of the network performance. This reprint presents a new algorithm for generating the most probable states. This new algorithm is a major improvement over the previous one in terms of efficiency and flexibility.

ABSTRACT: (U) This reprint presents an effective technique for the combined performance and reliability analysis of multimode computer systems. A reward rate (or performance level) is associated with each mode of operation. The switching between different modes is characterized by a continuous-time Markov chain. Different types of service-interruption interactions (as a result of mode switching) are considered. The authors consider the execution time of a given job on such a system and derive the distribution of its completion time. A useful dual relationship, between the completion time of a given job and the accumulated reward up to a given time is noted the use of this technique is demonstrated by means of a simple example.

EVJ58L

ABSTRACT: (U) The investigation of defects in Gallium Arsenide is pursued along three lines especially important for device processing: (a) origin and control of native midgap levels; (b) the role of vanadium in achieving semi-insulating GaAs; and (c) feasibility of achieving titanium doped semi-insulating III-V crystals. By employing high resolution optical absorption and DLTS measurements, we obtained an accurate calibration for the determination of EL2 by optical absorption. The new revised calibration factor is about 40% larger than the commonly used value. Vanadium in GaAs introduces only an acceptor level at (E sub c) -0.15 eV. Accordingly, the vanadium level cannot be involved in compensation mechanism responsible for semi-insulating GaAs. However, vanadium can help to achieve SI material due to its active role as a gettering center reducing concentration of SI. A search for an impurity with a midgap donor level has led to the discovery of new semi-insulating III-V compounds based on titanium doping. For the first time deep levels are identical due to titanium in GaAs and InP, and the midgap location (E sub c) -0.63 eV) of the Ti donor in InP can be used to obtain SI-InP with a resistivity exceeding -10 million ohm-cm.

UNCLASSIFIED REPORT

ABSTRACT: (U) The structural dynamic response of turbomachinery components to aerothermodynamic distortion induced excitations is of major concern in the design of advanced gas turbine engines. Rotor speeds at which these resonant forced responses occur can be predicted with Campbell diagrams. However, due to inadequacies of existing time-variant aerodynamic models, no accurate prediction can be made for the amplitude of the resulting vibrations and stresses. Therefore, this research program seeks to quantitatively investigate the fundamental phenomena relevant to aero thermodynamic distortion induced structural dynamic blade responses in multi-stage gas-turbine engine components. Flow physics of multi-stage blade row interactions is being experimentally investigated, with unique unsteady aerodynamic data obtained to understand, quantify, and discriminate the fundamental flow phenomena as well as to direct the modeling of advanced analyses. Data are being obtained to define both the potential and viscous flow interactions and the effect on the aerodynamic forcing function and the resulting unsteady aerodynamics of both rotor blades

and stator vanes. Analytically, a first principles capability to predict the vibrational response of blading due to aerodynamic excitations is being developed. Unsteady viscous flow analyses, appropriate for aerodynamic forced response predictions, are also being developed. Recent progress includes: stationary vane row experiments in a research compressor which investigate the fundamental multi-stage blade row interaction aerodynamics; and identification and modeling of a vortex street in the instantaneous wakes of rotor blades.

**ABSTRACT:** (U) The objective of the work reported is construction of zonal models for accurate prediction of turbulent flows in rapid-running computer programs. The work follows the ideas set down in the discussion of zonal modeling by S. J. Kline in Vol. II of the Proceedings of the 1980-81 AFOSR-Stanford Conference on Complex Turbulent Flows. This discussion noted that the fast-running models available lack sufficient span to predict all classes of turbulent flows of engineering importance in a standard, invariant form. It therefore suggested that the models be treated as zonal. In the zonal approach, the constants in the models are adjusted for each important zone of the flow, where the word zone implies a region with a particular type of flow physics. In the proposal for the work, it was also noted that the parametrization of the flows and the selection of appropriate constants would ultimately need to be guided by the domain over which accurate results could be obtained, and that might well be different from pre-conceptions embodied in conventional taxonomies of the flows.

ABSTRACT: (U) The author had three papers published, and three accepted for publication. Important advancement was made in the foundations of design theory. Difficult work (using ideal theory) was done on information matrices. The (very significant) paper on Parallel Flats Designs was revised, and so was another important paper on search decision rules. Work was also done in reliability and other fields. Keywords: Search linear models; Decision rule; Sensitivity revealing power; Coverings of affine spaces. (Author)

## UNCLASSIFIED REPORT

ABSTRACT: (U) Recent experimental observations have shown that a leading edge vortex on a delta wing at constant angle of attack consists of a series of discrete smaller vortices. These vortices pair, much the same as in a free shear layer. A device is proposed to modulate the shedding and the pairing of the discrete vortices by mechanically or acoustically perturbing the leading edge of a delta wing. By applying the perturbation to both leading edges, the total lift of a wing will be altered; alternatively, by using the perturbation preferentially on only one side of the wing, the rolling moment around the axis of symmetry of the aircraft is controlled. The proposed device will enable the pilot of a fighter aircraft to achieve a previously unattained degree of maneuverability. During the first phase of this research, experiments were conducted in both a water towing tank and a high speed wind tunnel. Flow visualization, fast-response velocity probe surveys, as well as force measurements were conducted to assess the performance of the proposed vortex control device and, more importantly at this early stage of the research, to understand the complex flow field under consideration. Keywords: Vortex control device; Lift control; Lift enhancement; Supermaneuverability.

UNCLASSIFIED REPORT

ABSTRACT: (U) By using a multiple-element scale/coherence decomposition of the Navier-Stokes equations, the essential characteristics of the large scale turbulent structure are computed in wall-bounded shear flows. The effect of small-scale turbulence structure is modeled and the large-scale turbulence structure is computed assuming weakly non-linear large-scale dynamics. The effects of large-scale non-linearity and the presence of wave-like elements in the flow are accounted for using perturbation theory. The resultant propagation, evolution (in the convected reference frame) and (statistical) occurrence of three-dimensional vortical instabilities are computed and compared to experimental data. Coherent structure reflective turbulence models will be constructed from this analysis.

UNCLASSIFIED REPORT

ABSTRACT: (U) A Navier-Stokes computational model of the time-development dynamics and heat transfer in a viscous sublayer had been developed. The main research objective is to determine the variation of turbulent Prandtl number across the sublayer. Experiments have been unable to define this variation, and existing theories differ greatly. The computational code uses prescribed temperature and velocity boundary conditions at the outer edge of the sublayer. Numerical computations of turbulent Prandtl number have been made for molecular Prandtl numbers ranging from 0.7 to 8 with zero pressure gradient, and for adverse, zero, and favorable pressure gradient, with a Prandtl number of 0.7. The results show a strong effect of molecular Prandtl number on turbulent Prandtl number a very near the wall; but only a relatively small effect of pressure gradient throughout the sublayer. For most practical computations of heat transfer, the simple assumption of the constant turbulent Prandtl number across the viscous sublayer appears adequate. Keywords: Fluid mechanics; Viscous sublayer; Navier-Stokes equation; Computational model.

ABSTRACT: (U) The detailed Al (111) surface structure  
depends upon the surface preparation. Steps, mosaics, and  
facets can form depending upon the sputtering time and  
the duration and temperature of annealing. In turn, the  
oxidation threshold of the surface depends upon the type  
and concentration of surface defects, with steps being  
the most important. Low energy electron diffraction (LEED)  
and Auger electron spectroscopy (AES) measurements of  
oxidation kinetics were made for several Al (111)  
surfaces to demonstrate the relationship between  
microscopic surface structure and surface oxidation.

ABSTRACT: (U) The initial oxidation of planar and faceted aluminum (111) surfaces was studied with low energy electron diffraction (LEED) and Auger electron spectroscopy (AES). The faceted surface was produced by rapidly heating the planar (111) surface to 773 K, and consisted of (111) and (221) planes. The planar surface showed first oxide-like aluminum at 50 L; however, the faceted surface showed first oxide at less than 10 L. The results are discussed in terms of the facet plane structures. ABSTRACT: (U) Studies continue on spatio-temporal interactions between briefly-flashed lines. The delayed facilitation we previously reported suggested that we were tapping a motion-detector system. However extensive experiments which failed to correlate our line interactions with the motion aftereffect and other well-known manifestations of motion detection have convinced us that we are measuring something different. We currently believe we may be tapping the moving-object detectors described by Burr. We have demonstrated that transient stimulation produces a substantial change in the configuration of inhibition and excitation, as revealed by summation between briefly-flashed lines. We have extended our studies of summation between lines to parafoveal vision. Unlike most visual functions, spatial summation in the periphery does not increase in direct proportion to cortical magnification. Based on our studies of summation, we predicted and observed that aliasing, though absent in the fovea, should be present in the parafovea. Studies of velocity discrimination suggest that there do not exist a small number of discrete velocity detectors, but rather a near-continuum of these. Keywords: Visual targets; Moving targets; Visual perception.

## UNCLASSIFIED REPORT

ABSTRACT: (U) The flow physics of multi-stage blade row interactions is being investigated. Unique data are being obtained to define the potential and viscous flow interactions and the effect on the aerodynamic forcing function and the unsteady aerodynamics of both rotors and stators. Analytically, a first principles capability to predict the vibrational response of blading is being developed. Also, unsteady viscous flow analyses for aerodynamic forcing response predictions are being developed. Progress during this reporting period include: vane row experiments which investigate fundamental blade row aerodynamics interactions; the identification and modeling of a vortex street structure in the instantaneous rotor wakes; preparations for rotating blade row experiments; the development and application of a locally analytic numerical method for steady viscous flows; the formulation of an unsteady incompressible viscous thin airfoil theory. Keywords: Unsteady aerodynamics, Aeroelasticity, Forced vibrations, Gas turbines, Turbomachinery.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report treats the numerical computation of cumulative distributions of random variables occurring primarily in communications, radar, and optics when their moment-generating or probability-generating functions are known. The cumulative distribution of a continuous random variable is expressed as a Laplace inversion integral of its moment-generating function, that of an integer-valued random variable as a contour integral that arises from Cauchy's theorem and whose integrand involves the probability-generating function. These integrals are evaluated by numerical quadrature along contours in the complex plane chosen for efficiency and convenience. Applications include radar detection probabilities with fading and unfading signals and fixed-threshold and constant-false-alarm-rate receivers; the distributions of the integrated output of a linear rectifier and of the filtered output of a quadratic rectifier; the error probability in a binary symmetric communication channel with intersymbol and cochannel interference; the distribution of shot noise; the distributions of the numbers of electrons emerging from photoelectric detectors, photomultipliers, and avalanche diodes; and significance probabilities in statistical rank tests.

on Decision and Control (24th), p208-211 Dec 85.

ABSTRACT: (U) There has recently been significant  
progress in various aspects of stochastic adaptive  
control. However, there are some deficiencies in this  
theory: (a) in all but the case of linear systems, the  
parameters estimates consists of minimum contrast or  
maximum likelihood estimates, or some modification of  
these, which are not necessarily easily computable in a  
recursive manner; (b) aside from the case of linear  
systems, virtually all of the work to date has involved  
complete (noise-less) state observations. This paper,  
begins to address (a) and (b) above by studying adaptive  
problems with incomplete state information, in which the  
state is a finite state Markov process. First consider  
the problem of adaptive state estimation, which is  
important both in its own right and in the context of  
adaptive stochastic control. Interesting results exist  
for linear discrete time and continuous time systems.

ABSTRACT: (U) New fast algorithms for high speed computation on the modern generation of supercomputers is essential. To meet these challenges new techniques are developed in numerical linear algebra and its applications for implementation on these new architectures. Significantly, applications of this work to practical problems of structural analysis and design and to least squares adjustments, estimation and digital filtering are also being investigated. The current objectives in structural analysis are to develop efficient and stable high speed algorithms for the design and analysis of large complex systems. Interest here is in developing stable alternatives to the often ill conditioned stiffness matrix approach to solving problems in elastic analysis and structural dynamics. For example, a comparative study is developed of the performances of seven alternative methods to the stiffness approach on the Alliant FX/8 and Cray X-MP systems. These methods involve various orthogonal factorization approaches as well as preconditioned conjugate gradient methods which completely avoid formation of the stiffness equations.

ABSTRACT: (U) It is important to be able to assess the reliability of a complex system in terms of the reliabilities of its components. This type of problem arises with increasing frequency in the analysis of telecommunication and distribution systems, which can be represented as networks. The present research employs an underlying algebraic structure to study network reliability problems and to develop new algorithms for their solution. Iterative techniques for calculating reliability (both exactly and approximately) have been developed for both general networks and a difficult class of specialized networks. These techniques allow the solution of fairly complex networks, ones that have previously resisted analysis. In addition, the underlying structure of network reliability problems has been approached by studying the combinatorial properties of a certain polynomial defined with respect to the underlying graph topology.

ABSTRACT: (U) The central theme involved in this work is the continuing study of certain fundamental features associated with the nonlinear wave propagation arising in and motivated by physical problems. The usefulness of the work is attested to by the varied applications, and wide areas of interest in physics, engineering and mathematics. The work accomplished involves wave propagation in a number of areas including fluid mechanics, plasma physics, theoretical physics, statistical mechanics, nonlinear optics, multidimensional solitons, multidimensional inverse problems, Painleve equations, direct linearizations of certain nonlinear wave equations, DBAR problems, Riemann-Hilbert boundary value problems, differential geometry, etc.

ABSTRACT: (U) This research sought to provide computational tools and procedures as the building blocks for a system to permit efficient solution and high resolution capture of flow structure in gasdynamic problems of realistically complex geometries. The research yielded a comparatively simple algebraic procedure for constructing two and three dimensional geometry fitted base level composite meshes in quadrilateral patches. The method provides complete control of coordinate distribution and gradient on all patch boundaries which may include slope discontinuities. A robust upwind implicit method (CSCM) was the basis to solve the multidimensional pseudo time dependent Euler or compressible Navier-Stokes equations. Research into solution algorithms for that upwind method yielded a more robust diagonally dominant (DDADI) approximate factorization that subsequently led to a family of rapidly convergent and data storage and management efficient relaxation schemes in two and three space dimensions. These operationally explicit and unconditionally stable upwind algorithms have led to a simple robust boundary procedure based on interpolation of conservative variable data from adjacent patches overlying interior patch boundaries where coordinates are discontinuous.

ABSTRACT: (U) Work is continuing primarily in gas phase turbulent mixing and chemical reactions. The liquid phase work to date is in its final stages of being analyzed and documented for dissemination in the form of archival publications. In the gas phase shear layer work, investigations are concentrating on shear layer free stream density ratio effects, finite kinetic rate (Damkohler number) effects, and a design effort in support of the planned extension of the work to supersonic flows. In jet flows, progress has been made in the gas phase laser Rayleigh scattering techniques developed for conserved scalar measurements down to diffusion space and time scales. A new technique has been developed under joint support with the Gas Research Institute that permits the imaging of soot sheets in turbulent flames and is being used to describe the combustion flame sheets in methane flames. Theoretical work in progress is addressing the finite chemical rate problem as well as the diffusion-limited shear layer mixing problem. Advances in our data acquisition capabilities during the last year are permitting higher temporal resolution measurements to be taken with digital image arrays.

## UNCLASSIFIED REPORT

ABSTRACT: (U) An investigation of the power of the Euler equations in the prediction of supersonic separated flows is presented. These equations are solved numerically for the highly vortical flow about simple bodies. Two sources of vorticity are studied: the first is the flow field shock system and the second is the vorticity shed into the flow field from a separating boundary layer. Both sources of vorticity are found to produce separation and vortices. In the case of shed vorticity the surface point from which the vorticity is shed (i.e., separation point) is determined empirically. Solutions obtained with both sources of vorticity are studied in detail, compared with each other, and with potential calculations and experimental data. Keywords: Fluid mechanics; Vortex flows; Supersonic flows.

ABSTRACT: (U) Dispersion effects are considered in addition to Location effects of factors in the inferential procedure of sequential factor screening experiments with  $m$  factors each at two levels under search linear models. Search designs in measuring Dispersion and Location effects of factors are presented for both stage one and stage two of factor screening experiments with  $4 < m < 10$ .

ABSTRACT: (U) Work on improving gradient-based methods for optical flow estimation has been completed. An understanding of how errors arise makes it possible to define the inherent limitations of the gradient-based technique, obtain estimates of the accuracy of computed values, enhance the performance of the technique, and demonstrate the informative value of some types of errors. Significant results have been achieved on the problems associated with motion-based segmentation. An approach based on understanding the three-dimensional scene structure leading to an edge in optical flow has been developed. As a result, it is possible to simultaneously detect edges and determine important three-dimensional properties of the associated scene surfaces. The methods which have been developed make it possible to distinguish between occluding and occluded surfaces at a boundary. This technique may make it possible to link image regions corresponding to a partially occluded object and to produce descriptions of object boundaries that are less affected by occlusion. In addition, being able to distinguish between occluding and occluded boundaries is a crucial step towards determining the three-dimensional position of surfaces. Keywords: image understanding, visual motion.

ABSTRACT: (U) New methods are presented for analysis and synthesis of control systems subject to structured uncertainties. The technical approach involves the structured singular value, as an analysis tool and H infinity as a synthesis tool. Alternative formulations are compared with the H infinity approach, extensions of mu to handle real parameter problems are presented, and the issue of the convergence of mu synthesis to a global optimum is studied. A comprehensive solution for the synthesis of general optimal controllers is given for linear lumped time-invariant systems. The existence of an optimal solution for H infinity optimization is proved, and some properties of this solution are discovered. The method called Euler's constant iteration is presented and its convergence properties are established. A new algorithm for solving a class of algebraic riccati equations is obtained. Explicit error bounds for model reduction in the synthesis process are derived. The constructions use standard matrix operations and linear algebra applied to state-space representations of linear systems.

UNCLASSIFIED REPORT

ABSTRACT: (U) A three-dimensional streamlike function/vorticity transport procedure has been developed to analyze two- and three-dimensional inviscid and viscous flows. Both the formulation and the numerical techniques used to solve these equations contain many of the advantages of interacting boundary layer theory for strongly interacting viscous and inviscid flows. An algorithm which involves the solution of two uncoupled Poisson/vorticity transport equation sets is described. An implicit line relaxation scheme is used to solve a 2 x 2 block-tridiagonal system for the Poisson and vorticity transport equations in each of the x- and z-directions. Solutions for 2-D and 3-D inviscid and viscous flows are compared with other numerical solutions demonstrating the stability and accuracy of the current procedure. Favorable agreement with the recently obtained 3-D interacting boundary layer solutions of Edwards demonstrates the overall accuracy of this new approach for 3-D viscous flows including flow separation. This streamlike function/vorticity transport procedure has been found to yield smooth solutions without the need to add explicit artificial viscosity. Keywords: stream function; finite difference coefficients; Navier Stokes equations.

ABSTRACT: (U) This paper is concerned with the analysis of synchronous, special purpose, multiple-processor systems, including, e.g., systolic arrays. There have been some results on this problem, especially by Mahesh and Rheinboldt. Our approach is different, combining ideas well known in linear system theory with certain graph-theoretical concepts from computer science. A by-product of our approach to the analysis program is a rigorous characterization of the notion of equivalence between iterative algorithms.

ABSTRACT: (U) A brief survey of the subject of network reliability is presented. Network reliability is the study of network performance when components of the network are subject to failures. The problem can be divided into two main parts: the modeling of component failures, the assumption that component failures are statistically independent is often made to simplify the problem. But this assumption is unrealistic in most real-world situations. In this survey, special attention is given to recent developments in modeling statistically dependent failures of network components. For reliability calculations, only analytical techniques are considered, and simulations are excluded. A brief classification of existing techniques is given. Since most network reliability problems are NP-hard, exact techniques to calculate network reliability can only handle problems of limited sizes, and therefore approximate techniques are of practical importance. Both exact and approximate techniques are covered in this survey.

ABSTRACT: (U) The structure of the low-lying electronic states of the unknown Si2C2 system is studied using full fourth-order Many Body Perturbation Theory (MBPT). It is concluded that the lowest-lying structure is a rhombus, superscript 1 A sub g state, which is ca. 12 kcal/mol lower than the linear superscript 3 sigma g (-) state. This is similar to the C4 system. The rhombus structure accommodates reluctance of silicon to form stable multiple bonds. Vibrational frequencies are reported.

ABSTRACT: (U) A Monte Carlo Fokker Planck Code is used to investigate the scattering loss of particles from a relativistic electron beam propagating in a low pressure air channel. Two special cases are examined. The first corresponds to an experiment in which a one cm radius, 90 KeV beam propagates in hydrogen channel of the same radius, 50 cm long with a density of 10 cm an da temperature of 0.5 eV assuming the interaction to take place only with the charged particles of the medium. It is shown that the beam will traverse such channel if the ionization drop s below 20% noting that for such parameters the channel pressure corresponds to few tens of millitons. The second case corresponds to what is referred to as the Ion Focused Regime where the pressure is about 0.1 torr. Scattering of beam particles by both neutral and charged particles is taken into account in this case as well as multiple scattering form neutral targets. It is shown that transmitted fraction is linearly proportional to the square of the channel radius, and the probability of multiple scattering increases with increasing channel radius.

UNCLASSIFIED REPORT

ABSTRACT: (U) After great progress related to soot  
formation in normal diffusion flames, studies of near  
sooting inverse diffusion flames were begun to determine  
controlling precursors. Stable, temperature controlled  
inverse diffusion flames have been successfully developed  
and numerous chemical samples extracted and analyzed.  
Observed trends are being studied. The side chain  
oxidation of n-butyl benzene was found to follow the same  
processes as the smaller n-alkyl benzenes; abstraction,  
alkyl group displacement and thermal cleavage. The  
results have led to development of a simple general,  
mechanistic model for the oxidation of n-alkyl benzenes.  
Combustion property observations of isolated boron  
droplets were extended to boron/JP-10 slurries with  
various solid loadings. Some physical understanding of  
observed droplet-burning and disruption behavior was  
developed. Quasi-spherical hollow shells of the boron  
agglomerate with blowholes support the hypothesis of the  
formation of the impermeable shell and subsequent  
disruption of the primary slurry droplet. Boron  
suspension (cloud) combustion in the hot reaction  
products of a flat-flame burner has been pursued. The  
boric acid fluctuation bands were identified  
spectroscopically, and conditions for their flame

ABSTRACT: (U) This document considers the discrete parameter process  $(x \text{ sub } t)$  satisfying the doubly stochastic model  $(X \text{ sub } T)$  satisfying the doubly stochastic model  $X \text{ sub } T = \phi \text{ sub } t \text{ sub } T - 1 \text{ t epsilon sub } t$ , where  $(\phi \text{ sub } t)$  and  $(\epsilon \text{ sub } t)$  are also stochastic processes. Necessary and sufficient conditions on  $(\phi \text{ sub } t)$  are given for  $(x \text{ sub } t)$  to be a second order process. When  $(x \text{ sub } t)$  is a strictly stationary process, some sufficient conditions in terms of  $(x \text{ sub } t)$  are given which guarantee the wide sense stationarity of  $(x \text{ sub } t)$ . It turns out that for these problems the distribution and dependence structure of the process  $(\log / \phi \text{ sub } t)$  play an important role. Keywords: Stochastic models.

## UNCLASSIFIED REPORT

ABSTRACT: (U) The three dimensional shock wave turbulent boundary layer interaction generated by several shock generators defined solely by angles has been carried out at a Mach number of 3. Interactions with thin boundary layers were used to obtain overall characteristics, while interactions with thick boundary layers permitted detailed high resolution surveys. Investigations of the surface pressure distribution measurements, surface flow visualization, and mean total head, yaw, and static pressure distributions through the flowfield. Major new data sets were obtained for the interaction of the shock wave generated by a 20 deg fin, and by a 24 deg wedge swept at 60 deg to the incoming flow. A series of tests were carried out to examine new concepts of three-dimensional interactions and extensive 'non-steady' results were obtained from the high frequency surface pressure distributions. Close coordination of the experiments with major computational efforts, support new concepts of flow structure and physics for these complex interactions. Keywords: Three-dimensional shock wave interactions; Conical similarity; Scaling laws; Conical/cylindrical boundary; Unsteady flow; Non-steady

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper examines the use of cluster analysis as a tool for system modularization. Several clustering techniques are discussed and used on two medium-size systems and a group of small projects. The small projects are presented because they provide examples (that will fit into a paper) of certain types of phenomena. Data bindings between the routines of the system provide the basis for the bindings. It appears that the clustering of data bindings provides a meaningful view of system modularization.

ABSTRACT: (U) This report covers the progress made in the first year of a three year study on the rapid solidification processing (RSP) of Al- and Mg based alloys. In this study, effort has been applied in three areas: (1) processing (both particulate production and consolidation) ; (2) Microstructural effects, and (3) Mechanical properties. The underlying objective has been to control the microstructure to obtain favorable mechanical properties. This will, perforce, entail a detailed understanding of the microstructures, as affected by factors such as alloy chemistry and processing variables, and, in turn, their effects on the mechanical properties. The microstructural changes which occur in heat-treated, as-rapidly solidified materials, as well as those in materials consolidated, either by extrusion or by the relatively new technique of dynamic compaction, have been investigated. The alloy systems studied include: (1) high modulus Al alloys, namely, Al-Mn and Al-Be, (2) Al alloys for elevated temperature applications, namely, Al-8Fe-2Mo, and (3) Mg alloys for elevated temperature applications, namely, Mg-20Gd and Mg-Li-Si. The report is divided into three major sections: (1) Brief overview of RSP of individual alloys, (2) Results, and (3) Future work. Individual sections are further subdivided as appropriate.

ABSTRACT: (U) First a simple practical procedure for approximating a stationary Gaussian process over a finite interval by a trigonometric polynomial with predetermined error is described. The approximation is then used to calculate the distribution of the maximum, using a novel Monte Carlo method with a control variable which drastically reduces the variance. Finally, the outlined approach is compared to the moving-average technique and shown to be superior for continuous-time, narrow-band processes.

**ABSTRACT:** (U) The asymptotic properties of extensions of the type of distributed or decentralized stochastic approximation proposed are developed. Such algorithms have numerous potential applications in decentralized estimation, detection and adaptive control, or in decentralized Monte Carlo simulation for system optimization (where they can exploit the possibilities of parallel processing). The structure involves several isolated processors (recursive algorithms) who communicate to each other asynchronously and at random intervals. The asymptotic (small gain) properties are derived. The communication intervals need not be strictly bounded and they and the system noise can depend on the (communicating) system state. State space constraints are also handled. In many applications, the dynamical terms are merely indicator functions, or have other types of discontinuities. The typical such case is also treated. The linear stochastic differential equation satisfied by the (interpolated) asymptotic normalized error sequence is derived, and issued to compare alternative algorithms and communication strategies. Weak convergence methods

UNCLASSIFIED REPORT

ABSTRACT (U) The present effort has led to the development of a numerical procedure of the stage flow field based upon solution of the Navier-Stokes equations. The specific case considered is the basic case in which two-dimensional flow and equal rotor and stator pitch are assumed. The procedure developed is capable of obtaining periodic solutions for a grid of 7500 points within ten CPU minutes of Cray run time. This represents a very efficient technique which will permit runs of this type on a regular basis, and which will allow extension to either three dimensions or to stages in which rotor and stator have unequal pitch and the multiple stages. The results obtained show the qualitatively expected features. Periodicity was obtained essentially within five cycles. The major effect of the interaction to the specific case considered appeared in the leading edge region of the downstream rotor blade. Significant perturbation pressures were noted,  $\Delta C_p$  approx. = 0.4, which has major implications regarding unsteady loading and unsteady fluid structure interaction. The concentration of the interaction effect in the leading edge has particular significance in regard to unsteady pitching moment. Although less significant, unsteady effects were noted over the aft portion of the trailing blade, as well

UNCLASSIFIED REPORT

ABSTRACT: (U) This report begins with the development of the time and temperature-dependent effective constitutive equations for unidirectional fiber composites. The fibers were represented as transversely isotropic and linearly elastic, temperature dependent elements. The deviatoric components of the isotropic matrix material were treated as linearly viscoelastic and thermorheologically complex, while the dilatation components were represented as elastic and temperature dependent. Numerical simulations of a series of isothermal creep tests were performed to determine the effective creep compliance parameters of the composite constitutive equations. The macro-mechanical response of a composite structural element, as predicted by the effective constitutive equations and their derived parameters, was then verified using results computed using a micro-mechanical model which explicitly included the fiber and matrix as discrete phases. To determine the potential existence and form of a composite complex modulus, the response of unidirectional composite structural elements to simultaneous sinusoidal temperature and mechanical loads was investigated. Finally, solutions of free vibration and transient dynamic analyses of some simple composite structures were

performed to examine the effects of the thermoviscoelastic behavior on the damped response of some simple composite structures.

UNCLASSIFIED REPORT

ABSTRACT (U) Variational Principles for dynamics of the fluid-saturated porous media are derived assuming that soil is linear elastic and deformation is small. Starting with basic mathematical concepts related to the inverse problem of calculus of variation and following the methodology proposed by Sandhu for coupled problems, general variational principles for the problem are developed. Complementary as well as direct formulation are discussed with reference to finite element approximation space and the excitation are allowed for. Extensions of the variational principles to relax smoothness requirements on certain field variables are introduced along with some specializations. Keywords: Coupled problems; Elasticity; Fluid-saturated solids; Seepage; Soil dynamics.

ABSTRACT (U) This project is to study the estimation and control of elastic systems composed of beams and plates in order to develop efficient and accurate estimation and control algorithms. Results have been obtained for the estimation in static beams and plates, control and location of actuators for static beams and plates, and identifiability for discrete approximations of second order elliptic boundary value problems. Currently testing codes are being developed for numerical experimentation for estimation of damping and elastic coefficients in dynamic linear plate models, estimation of boundary parameters for second order elliptic problems, estimation of elastic coefficients in cantilevered beams using perturbed boundary conditions, optimal location of actuators for the control of beams, and control of plates through forces at points and forces distributed over sets of small measure and curves. The plan is to next investigate boundary control and estimation, estimation and control in structures use of friction as an active control, and parallelization of estimation and control algorithms.

ABSTRACT (U) The subject of the current research effort is the development of a theory of optical computing. It is generally agreed that optical computing has an advantage over digital computing in situations where parallelism can be exploited. The canonical examples are matrix-vector multiplication and matrix-matrix multiplication. If the matrices are both square and of size  $n \times n$  then outer-product decomposition achieves a saving in computational time because the  $M2$  inner products can be evaluated concurrently. It is outlined in Section 1. Our second completed contribution is the development of a tractable mathematical model of an optical system (assuming incoherent light operations and its use into an investigation of the inherent limits of computation of such a system in terms of a lower bound on the simultaneous resources of volume and computing time. Keywords: Electrooptical; Matrix vector multiplication; Canonical

ABSTRACT (U) Continuous fiber composite laminates are known to undergo a substantial amount of complex load-induced damage which can adversely affect component performance. Therefore, it is desirable to develop new models capable of accounting for the effect of damage on materials properties. The objective of this research is to develop an accurate damage model for predicting strength and stiffness of continuous fiber composite media subjected to fatigue or monotonic loading and to verify this model with experimental results obtained from composite specimens of selected geometry and makeup to be described herein. Keywords: Laminates analysis, failure, finite element methods, internal state variables, plasticity.

ABSTRACT: (U) Fluorescence data which sample virtually the entire ground state potential wells for C12 and I2 are least-squares analyzed in terms of mixed representations-polynomials in  $v + 1/2$  at low  $v$  and near-dissociation expansions at high  $v$ . Smooth functional expressions for the vibrational energy and rotational constant are obtained by means of exact constraints introduced into the fits by Lagrange's method of undetermined multipliers. The resulting least-squares equations are less ill-conditioned than those often encountered in fitting to high-order polynomials, and the smoothness constraints are satisfied with negligible statistical penalty. The results of the fits are examined for their extrapolating ability and their sensitivity to changes in the orders of the component functions and in the low- $v$  to high- $v$  switchover point.

UNCLASSIFIED REPORT

ABSTRACT: (U) The electron attachment rate constants of SO<sub>2</sub>, CS<sub>2</sub>, and SOCl<sub>2</sub> in buffer gases of Ar, N<sub>2</sub>, and CH<sub>4</sub> were measured at various E/N by a parallel plate drift tube electron swarm technique. The initial electron swarm was produced by irradiation of cathode with excimer laser. The electron attachment processes for the electronegative gases studied were investigated. The transient increase of electron conduction current by photoelectron detachment of negative ions in the discharge medium of SOCl<sub>2</sub> in N<sub>2</sub> was observed. This switching is useful for the development of opening switches. Keywords: Electron production; Electron attachment; Electron diffusion; Charge recombination; Electron conduction current; Negative ion; Electron swarm; Electrical discharge; Opening switches; Electron attaching gas; Excimer laser; Parallel-plate drift-tube apparatus; Computer modeling.

ABSTRACT: (U) This grant, devoted to the subject of laminar flows in three dimensions. During this period, efforts were first focused on settling the fundamental question of three dimensional separation. New evidences continue to lend support to our open separation concept. Later emphasis was shifted to the preparation of a monograph to bring together the newly developed materials on the subject of three dimensional laminar flows into a unified treatment.

UNCLASSIFIED REPORT

ABSTRACT: (U) In the area of consumption and portfolio problem in continuous time, Merton is the most widely cited paper. It is an important paper because of its many significant contributions. Among these was the provision of explicit solutions for utility functions in the HARA family specified in equation (43) of Merton's paper. These solutions in the form of lengthy formulas were simply stated without any derivation. Perhaps, because of this, some errors went undetected. While some minor errors were corrected in Merton, the purpose of this note is to delineate the subfamily of HARA utility functions for which the explicit solution obtained in Section 6 of Merton's paper are correct and the remaining subfamily for which they are not.

TR-86-2168

UNCLASSIFIED REPORT

ABSTRACT: (U) An asymptotic analysis is given of the compressible, laminar boundary layer flow of a dilute gas particle mixture over a semi-infinite flat plate. The analysis extends existing work by considering more realistic drag and heat transfer relations than those provided by Stokes. A more general viscosity temperature expression is also incorporated into the analysis. The solution involves a series expansion in terms of the slip parameter of the particles. The numerical results, including the zeroth and first order approximations for the gas and particle phases, are presented for the two limiting regimes: the large slip limit near the leading edge and the small slip limit far downstream. Significant effects on the flow produced by the particles with Stokes' and non-Stokes' relations are studied and clarified. The effects of some nondimensional similarity parameters, such as the Reynolds, Prandtl and Eckert numbers, on the two phase boundary layer flow are discussed. Keywords: Dusty gas flows; Two phase flows; Boundary layer flows; Partial differential equations; Numerical analysis; Canada.

TASK NO. B2

ABSTRACT: (U) A continuum structure function is a  
nondimensional mapping from the unit hypercube to the unit  
interval. The theory of such functions generalizes the  
traditional theory of binary and multistate structure  
functions, permitting more realistic and flexible  
modeling of systems subject to reliability growth,  
component degradation and partial availability. A theory  
of modules (i.e. subsystems) was developed and, various  
sets of bounds were calculated on the distribution of the  
structure function when the component states are random  
variables. Axiomatic characterizations of two important  
special cases are deduced a definition derived of the  
reliability importance of the various components, a  
theory of cannibalization deduced.

TR-86-2182

ABSTRACT: (U) It is well known that composite materials  
suffer complex damage when they are subjected to either  
monotonic or fatigue loading. This damage affects both  
the velocity and attenuation of ultrasonic waves. The  
primary objective of this research is to correlate the  
damage states with the changes in the velocity and  
attenuation. Once this has been accomplished the pair of  
ultrasonic parameters becomes a measure of the damage. A  
particular damage mode, namely, transverse cracking has  
been examined in detail. The Through-the-thickness  
attenuation was found to be a very sensitive measure of  
transverse cracking. In order to study the influence of  
damage axial stiffness, we have studied the propagation  
of Lamb waves. As expected the transverse cracking  
significantly reduces the axial stiffness. Finally, a new  
experimental technique for measuring speed and  
attenuation of ultrasonic waves in laminates of very  
small thickness has been developed. Key Words: Ultrasonic  
nondestructive testing, Lamb waves.

TASK NO. B1

MONITOR: AFOSR TR-86-2112

UNCLASSIFIED REPORT

ABSTRACT: (U) A nonlinear finite element analysis procedure already developed for planar mechanisms is being modified to handle complex mechanisms with sliding masses and mechanisms operating at relatively high speeds. Progress is also being made in developing a suitable nonlinear finite element analysis procedure for three-dimensional mechanisms. In both cases the analysis takes into account the effects of geometric and material nonlinearities, vibrational effects and coupling of deformations. In the optimal design area, a new algorithm has been developed for finding the minimum of a sum-of-squares objective function subject to general nonlinear constraints. The solution of preliminary examples indicate good results in terms of the total number of objective function evaluations to obtain an optimal design. Complete details of these investigations are included in the Appendix. To meet the extraordinary computational needs of this project, a separate research VAX 11/78S Computer and peripheral equipment were made available through a DoD research grant. The National Science Foundation also provided funds for some additional equipment as well as computational time on a supercomputer.

ABSTRACT: (U) Ion implanted contiguous disk bubble memory devices, which were designed and fabricated are being tested. The aim of this testing is to identify the strongest and the weakest elements of these circuits with the hope of designing a fully operational four micron period device. The initial phase of testing has involved obtaining minor loop propagation bias margins, observing the failure mechanisms and attempting to discover the reasons for these failure. Future work will include similar observation for generation, transfer and detection including both bias and current amplitude and phase margins.

UNCLASSIFIED REPORT

ABSTRACT: (U) A summary of results is presented on the subject of damage development in metal and polymer matrix composite laminates. The following technical developments are described: (i) Evaluation of crack densities, stiffness changes, and fiber stresses caused by cyclic loading in three 8061-0 A18 laminates, with 08 (0/90)2s, and (0/+ or - 45/90/0 + or - 45/1/290s) layers. This problem is solved in an incremental way, with regard for interaction between plastic deformation and matrix crack growth in individual plies. Saturation damage states are predicted at different levels of steady cyclic loading. Good comparison is obtained with available experimental data. (ii) Analysis of first ply failure in polymer matrix composites. The influence of ply thickness on strength is predicted in terms of flaw nucleation mechanisms, and (iii) Analysis of distributed damage caused in a composite ply by either transverse cracks or fiber breaks. Several methods, such as self-consistent estimates, shear lag approximations, crack array models, and finite element analysis of cracks in an embedded ply were employed. It was found that these methods give very similar predictions of stiffness reductions of plies and laminates, and that these predictions are in good

UNCLASSIFIED REPORT

ABSTRACT: (U) Although Bodner's viscoplastic constitutive equation is useful because it does not require a yield criterion, it also exhibits deficiencies related to hardening behavior. Two new constitutive forms were developed from Bodner's equation to address this problem. The general approach employed scaling relations to define macrostructural response in terms of microstructural evolution. The first new equation expresses strain rate as a function of scaled microstructural models available from the metallurgical literature, and is useful for structural analyses. The second new equation represents a nonlocal model for viscoplasticity. It describes the evolution of internal stress field fluctuations in terms of scaled hardening and damage state variables, and contains the basis for a new material state tensor. The two new equations were verified by comparison to creep data for a steel alloy and aluminum, respectively. Keywords: Bodner's theory, Microstructure; Fractals; Scalings; Nonlocal stress polarizations.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report examined current computerized analysis techniques for slabs on grade. The focus of investigations presented is the application of the three dimensional finite element program GEOSYS for the analysis of a slab, resting on a stress dependent elastic solid foundation. This model can be used to establish baseline structural response data, representative of complex boundary and support conditions, thereby validating conclusions reached on the basis of two dimensional analysis. Many computer runs were conducted to develop user guidelines for the fruitful utilization of the three dimensional approach. Effects considered include mesh fineness and gradation, subgrade extent, boundary conditions, etc. The three fundamental loading conditions, viz. interior, edge and corner, are examined. Two typical single and multi-wheel U.S. Air Force aircraft are employed (F-15 and C-141). An iterative scheme is introduced to account for subgrade stress dependence. The effect of stress softening, typical of cohesive soils, is evaluated and discussed. A number of interesting observations are made, and their bearing on current analysis and design approaches is considered. Two broad areas for future research are identified. The relevance and need of the GEOSYS model to future pavement research/development activities is established. Keywords:

## UNCLASSIFIED REPORT

ABSTRACT: (U) This program dealt with the development and application of new approaches for producing and evaluating semi-empirical (lumped parameter) mathematical models of physical processes. Procedures using local sensitivity gradient methods were used to study the existing lumped kinetic models for the moist carbon monoxide oxidation to show that transport processes can cause oversimplified lumped models derived from homogeneous kinetics to fail when applied to flame propagation systems. New models are under development which will include the appropriate level of detail. A Lie group formalism was developed to address global parameter space mapping issues for first order differential equations. Keywords: Lie Algebra.

## UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Prepared in cooperation with Eli Lilly & Company.

ABSTRACT: (U) Assay data are often fit by a nonlinear regression model incorporating heterogeneity of variance, as in radioimmunoassay, for example. Typically, the standard deviation of the response is taken to be proportional to a power theta of the mean. There is considerable empirical evidence suggesting that for assays of a reasonable size, how one estimates the parameter theta does not greatly affect how well one estimates the mean regression function. An additional component of assay analysis is the estimation of auxiliary constructs such as the minimum detectable concentration, for which many definitions exist; we focus on one such definition. The minimum detectable concentration depends both on theta and the mean regression function. We compare three standard methods of estimating the parameter theta due to Rodbard (1978), Raab (1981a) and Carroll and Ruppert (1982b). When duplicate counts are taken at each concentration, the first method is only 20% efficient asymptotically in comparison to the third, and the resulting estimate of the minimum detectable concentration is asymptotically 3.

ABSTRACT: (U) In the plasma studies area, the model for carbon deposition from methane plasmas was extended to include homogeneous chemical kinetics of both neutral and ionized species, and it was tested with extensive plasma characterization experiments varying plasma excitation and flow parameters. In addition, experiments were completed on methane-hydrogen plasmas, and will be compared to the model. Thermal desorption and dissociation kinetic studies of propylene on silicon surfaces has produced several significant results. It was found that surface reactivity could be controlled by creating damage sites via ion bombardment or by capping such sites with atomic hydrogen. In addition, the adsorption of propane and methane were studied at 120K and compared to the double-bonded propylene using kinetic uptake experiments and Auger surface studies. It was found that no sticking is obtained for hydrocarbon molecules that do not have C=C double bonds. This program has produced several journal articles as well as numerous invited and contributed conference talks and papers. Four preprints are attached which describe the main accomplishments of this program during this reporting period.

ABSTRACT: (U) A numerical method to solve the perfect gas Navier-Stokes equations for hypersonic flows past three-dimensional blunt bodies has been developed. The numerical method uses flux-splitting and shock-fitting with an implicit Gauss-Seidel line-relaxation procedure to accelerate convergence. The technique has been used to solve the flow field over a spherically blunted biconic and the X24C-100 hypersonic research vehicle. The method has been shown to reduce the number of iterations required to achieve convergence of a typical problem by a factor of about one hundred over an explicit method. The scheme also shows a potential advantage over approximately factored implicit methods. The key advantage of this technique is that the low number of iterations required for convergence does not increase as mesh resolution is refined. ABSTRACT: (U) The goal of this research is to develop vortex methods for numerical simulation of multi-dimensional, time-dependent turbulent chemically-reacting flows with high temporal and spatial accuracy. Of particular interest is turbulent shear flows associated with the propagation of turbulent flames in combustion systems. Vortex methods are developed and incorporated in a numerical simulations of turbulent reacting flow, and applied to study the propagation and stability of turbulent flames in different geometrical configurations. At high Damkohler number, a dynamic thin flame model is used, while for slower reactions, the vortex scheme is extended to solve the energy and species equations with finite rate chemical reaction in a Lagrangian particle form. Results have been obtained for a confined mixing layer, a recirculating flow over a rearward facing step, and a confined shallow cavity. Detailed analyses have been performed to validate the numerical schemes and to study the structure and stability of these flows. The scheme has been extended to three dimension flow and an investigation of the transition to turbulence in an axisymmetric shear layer has been initiated. Currently, the combustion algorithm is being linked to the vortex simulation to predict the interaction between the

SUPPLEMENTARY NOTE: Pub. in SIAM Jnl. on Numerical Analysis, v22 n6 p1082-1106 Dec 85.

ABSTRACT: (U) In the p-version of the finite element method, the triangulation of the domain is fixed and the degree  $p$  of the local approximating polynomial is increased. This is in contrast with the h-version in which the degree  $p$  is fixed and the maximum diameter  $h$  of all triangles is allowed to go to zero. We derive a convergence result for the approximating solution to the biharmonic equation when using the p-version. This result shows that the rate of convergence for the p-version with quasi-uniform mesh in the approximation of singular solutions caused by corners. This result which applies to problems which require C sub 1 global continuity is analogous to an earlier result which applied to C sub 0 problems. Applications to several benchmark problems in plate bending are presented. Sample results are examined and compared with theoretical predictions. (Author)

ABSTRACT: (U) An experiment was conducted to study the aerodynamic response of a wing to large amplitude pitching motions, including dynamic stall. A two-dimensional model was tested at Mach numbers of 0.2, 0.3, and 0.4, corresponding to Reynolds numbers between  $2 \times 10^5$  and  $4 \times 10^6$ . A total of 48 unsteady conditions were studied, including both sinusoidal oscillations and constant pitch rate ramps. The ramp motions ranged up to 0 to 30 deg at pitch rates between 17.8 and 360 deg/sec. A preliminary analysis of the results shows significant effects of pitch rate and Mach number on the surface pressures, integrated airloads, and locations of boundary layer transition and separation. A pressure oscillation was detected in the post stall region that appears to result from periodic vortex shedding that has synchronized to the imposed pitching motion. A more detailed analysis of these results will be conducted during the remainder of this activity. Keywords: Unsteady aerodynamics; Dynamic stall; Aerodynamic testing; Unsteady measurement techniques.

ABSTRACT: (U) This document develops a general theory for variance function estimation in regression. Most methods in common use are included in our development. The general qualitative conclusions are these. First, most variance function estimation procedures can be looked upon as regressions with responses being transformation of absolute residuals from a preliminary fit or sample standard deviations from replicates at a design point. Our conclusion is that the former is typically more efficient, but not uniformly so. Secondly, for variance function estimates based on transformations of absolute residuals, we show that efficiency is a monotone function of the efficiency of the fit from which the residuals are formed, at least for symmetric errors. Our conclusion is that one should iterate so that the residuals are based on generalized least squares. Finally, robustness issues are of even more importance here than in estimation of a regression function for the mean. The loss of efficiency of the standard method away from the normal distribution is much more rapid than in the regression problem. Keywords: quality control; heteroscedasticity.

ABSTRACT: (U) This research has aimed at providing computational tools and procedures as the building blocks for a system to permit efficient solution and high resolution capture of flow structure in gas dynamic problems of realistically complex geometries. The research yielded a comparatively simple algebraic procedure for constructing two dimensional geometry fitted base level composite meshes in quadrilateral patches. The method provides complete control of coordinate distribution and gradient on all patch boundaries which may include slope discontinuities. A robust upwind implicit method (CSCM) was the basis to solve the two dimensional pseudo time dependent Euler or compressible Navier Stokes equations. Research into solution algorithms for that upwind method yielded a more robust diagonally dominant (DDADI) approximate factorization that subsequently led to a family of rapidly convergent and data storage and management efficient relaxation schemes. These effectively explicit and unconditionally stable upwind algorithms have led to a simple robust boundary procedure based on interpolation of conservative variable data from other patches overlying interior patch boundaries where coordinates are discontinuous. Results of preliminary tests with model problems show the desired accuracy and great potential

ABSTRACT: (U) The first quarter of the OCCAM contract effort was especially fruitful. Several pure results were obtained in optical conceptual computing and associative memories. These results include the formal definitions of fuzzy associative memories, the first-principles proof that differential Habbian learning subsumes standard Habbian learning, the construction of a new optically computable fuzzy integral, a quantitative theory of fuzzy cognitive map combination and inferencing, the design and preliminary simulation of a novel all-optical dynamical associative memory, the first optical design for implementing the fundamental fuzzy set/logic operations of pairwise minimum and maximum, the design and preliminary simulation of a translation, rotation, and scale invariant optical preprocessor suitable for pattern recognition by associative memory, and the design and construction of an associative memory demonstration computer board. Several of these results are currently in preparation as technical papers. Some have been presented at professional speaking engagements.

UNCLASSIFIED REPORT

ABSTRACT: (U) The goal of the Optical Symbolic Processor for Expert System Execution program is to develop concepts for optical computers which can perform real-time symbolic processing. The program is divided into two sections, architecture development and development of a device for reconfigurable interconnects. In the first quarter of the program, only architecture development work was performed. The approach for this phase of the program has been to examine computational models of computer languages and determine the primitive operations required. Possible optical implementations of these primitives were then examined and evaluated. In general, a top down approach was taken with the goal of a direct optical implementation of the desired primitive operations. It was found that the computational requirements of logic languages and functional languages are primitive operations which involve manipulation of complex data structures such as graphs and trees, and that the execution of the languages can be described as manipulations of those data structures. The representations of the complex data structures imply that the representations must be exact (digital) and that some means to denote connections between data items, such as pointers, is required. Since the representation between data items is more important than the actual items stored,

the most important functions involve the manipulation of the data structures. Examination of the optical architectures available to represent and implement the functions identified showed some way to perform location addressable memory was needed.

UNCLASSIFIED REPORT

ABSTRACT: (U) A finite difference method is used to investigate compressible, laminar boundary layer flows of a dilute dusty gas over a semi-infinite flat plate. Details are given of the implicit finite difference schemes as well as the boundary conditions, initial conditions and compatibility conditions for solving the gas particle boundary layer equations. The flow profiles for both the gas and particle phases were obtained numerically along the whole length of the plate from the leading edge to far downstream of it. The finite difference solutions in the large slip region and the small slip region are compared with the asymptotic solutions and good agreement is achieved. The boundary layer characteristics of interest, including the wall shear stress, the wall heat transfer rate and the displacement thickness, are calculated. The alteration of the flow properties owing to the presence of particles is discussed in detail. It was found that the boundary layer flow of a dusty gas can be divided into three distinct flow regimes which are characterized by quasi-frozen, nonequilibrium and quasi-equilibrium flows and that at a critical distance from the leading edge the particle

velocity at the wall decelerates to zero and near equilibrium is achieved between the gas and particle flows. For the laminar boundary layer of a dusty gas, the shear stress and the heat transfer at the wall are increased and the displacement thickness is decreased compared with the pure gas case alone. (Canada).

ABSTRACT: (U) Development of a fundamental understanding of turbulence-chemistry interactions remains one of the most important and challenging problems in turbulent reacting flows. This program couples laser based measurements and computer modeling of well-characterized laboratory-scale jet diffusion flames to study the effects of finite-rate chemistry and localized extinction in turbulent combustion. The long-range goal is to use this fundamental understanding for control of lean and high-altitude blow out in gas-turbine engines. The results of the first year of this program include: 1) Improving the data base for CO/H<sub>2</sub>/N<sub>2</sub> turbulent jet diffusion flames by analyzing direct measurements of CO<sub>2</sub> concentrations from Stokes vibrational Raman intensities and by comparing two independent methods of determining temperatures from the Raman data; 2) testing of the stretched laminar flamelet concept in turbulent diffusion flames by comparison of instantaneous and conditionally averaged Raman measurements in turbulent H<sub>2</sub> and CO/H<sub>2</sub>/N<sub>2</sub> jet diffusion flame calculations and measurements; and 3) testing of a diffusion flame pilot for stabilization of turbulent jet flames at high Reynolds number.

UNCLASSIFIED REPORT

ABSTRACT: (U) Work is continuing in both gas phase and liquid phase turbulent mixing and chemical reactions. In the gas phase shear layer work, our investigations are concentrating on shear layer free stream density ratio effects, finite kinetic rate (Damkohler number) effects, and heat release effects the latter up to a temperature rise in the combustion zone of the order of 1,000K. In jet flows, the development of laser Rayleigh scattering techniques is progressing towards conserved scalar measurements down to diffusion space and time scales. In the liquid phase work, laser induced fluorescence measurements in both shear layer and jet flows have yielded considerable new information on the mixing process and statistics, permitting direct estimates as the probability density function in both cases. Theoretical work in progress is addressing the finite chemical rate problem as well as the diffusion limited shear layer mixing problem. Keywords: Turbulence; Flame; Damkohler number; Shear Layer; Jet Combustion.

ABSTRACT: (U) During the first year of the project, the multiphoton spectroscopy of atomic fluorine was investigated to determine if three photon excitation could be used for remote detection applications. The first observation of resonantly enhanced multiphoton ionization (REMPI) of atomic fluorine is reported. Four excited states are observed for dye laser wavelengths in the range of 286 nm corresponding to a three photon resonant transition in a 3+2 photon ionization process. REMPI spectra of molecular fluorine in a 3+1 photon process are also observed. The resonant excited states in the spectra have been identified using absorption spectra published in the literature. In the present experiment, it is estimated that 0.03 millitorr of fluorine atoms can be detected with a signal to noise ratio of two. An apparatus is under development to test the techniques of two photon excited fluorescence and coherent anti Stokes Raman spectroscopy for detection of atomic fluorine.

ABSTRACT: (U) This document to introduce the problem with an example. How should we design an experiment to compare 4 test treatments with a control, using 18 experimental units? As a statistical question we will not be able to answer it unless it is asked in a more precise manner. To begin with we need to postulate a model for the response observed upon application of a treatment or control, to an experimental unit. This paper considers three possible models: 1) 0-way elimination of heterogeneity model in which all experimental units are homogeneous before application of treatments, 2) 1-way elimination of heterogeneity model in which the experimental units can be divided into several homogeneous blocks, and 3) 2-way elimination of heterogeneity model in which the experimental units can be conceptually arranged according to rows and columns.

ABSTRACT: (U) The aims of our study as outlined in our original proposal were the following: (1) Carry out an initial study of suitably chosen LANDSAT data over both land and sea; (2) Develop the first step in the evolution of semi-automatic computer algorithms to obtain cloud morphology data on a global and long-term basis; (3) Provide a basis for future coordinated satellite, air and ground-based experiments on cloud field properties. (4) Test and improve the modelling of cloud field optical properties for various purposes; (5) Use the data for testing models of atmospheric dynamics on various scales and to develop methods for using cloud morphology data as diagnostics for large scale atmospheric characteristics. These aims have been carried out for the most part.

EVJ56L

ABSTRACT: (U) Algorithms were developed for the generation of grids in 2D and 3D. The 3D code development involved extensive use of computer Symbolic Manipulation. A rigorous code validation procedure was developed. A controversy on the effect of strong coordinate stretching was resolved, with proof that the order of accuracy is not reduced. The contention that a well known method always produces a nonfolded grid was disproven. A family of adaptive algorithms was developed, involving both interior adaption and especially boundary adaption. Initial work was begun on an extension of the variational approach to grid generation. The grid generation algorithms have been applied in the 2D and 3D ELF codes (Electric Field) used in the design of laser electrodes and switches. Applications are in the Pulsed Power area, including SDI research and development. Keywords: adaptive grid generation; elliptic grid generation; symbolic manipulation; code verification; variational formulation; lasers; electrode design.

ABSTRACT: (U) This document considers fitting a straight line to data when the variances are not constant. In most fields, it is fairly common folklore that how one estimates the variances does not matter too much when estimating the regression function. While this may be true, most problems do not stop with estimating the slope and intercept. Indeed, the ultimate goal of a study may be a prediction or a calibration. It is shown by an example that how one handles the variance function can have large effects. The point is almost trivial, but so often ignored that it is worth documenting. Additionally, this points out that one ought to spend time trying to understand the structure of the variability, a theoretical field that is not particularly well developed. Keywords: weighted least squares; heteroscedasticity.

ABSTRACT: (U) The main task of this program is to develop powerful methods of representing, generating, and executing hierarchical plans that contain parallel actions. Execution involves monitoring the state of the world and, possibly, replanning if things do not proceed as expected. Over the last few years, we have designed and implemented a system called SIPE (System for Interactive Planning and Execution Monitoring), the purpose of which is to demonstrate the heuristic adequacy of our approach to this problem. Our basic in procedural networks. Our research this year concentrated on improving SIPE to provide a high-level reasoning capability for a mobile robot. Topics include: Sonar interfaces; Low-level sonar preception; Improving the replanning algorithm; Matching variables with PREO constraints; Efficiency considerations. Keywords: Control systems; Artificial intelligence.

ABSTRACT: (U) A theory for robust filtering and smoothing is formulated that combines the qualitative robustness theory with the theory of saddle point games. This theory finds robust filters for certain contaminated classes of stochastic processes. Robust predictors, interpolators, and filters are designed for various classes of vector stationary processes with contaminated spectra. Measures of breakdown points and curves, efficiency, and performance variation within the classes are produced. A variety of multiple access transmission protocols are designed for various levels of available feedback and feedback sensing. The studies include asymptotically many user models. Limited sensing algorithms are devised with the with the highest existing throughput, to this point in time, and with robust characteristics in the presence of feedback errors. A unified methodology for the delay analysis of a big variety of random access algorithms is devised.

ABSTRACT: (U) An in-depth discussion of the effects and mechanisms of action of some toxic agents on the cytoskeleton is provided. Mammalian and other eukaryotic cells contain protein networks within the cytoplasm comprised of microfilaments, intermediate filaments, and microtubules. These components of the cytoskeleton play a key role in cell shape, motility, intracellular organization and transport, and cell division. Because of the complex functional roles of the cytoskeleton which vary with cell type, degree of differentiation, and cell cycle, its disruption may result in a variety of cellular changes. This expanding field in cell biology has already attracted the interest of toxicologists and environmental health scientists as a potentially fruitful area of research. There is mounting evidence that certain toxic and chemotherapeutic compounds, as well as physical agents such as radiation and hydrostatic pressure, disrupt the normal structure and function of the cytoskeleton.

UNCLASSIFIED REPORT

ABSTRACT: (U) The primary aim of the program is to discover materials and/or structures with large, fast nonlinear optic susceptibilities. Such elements are required in optical signal processing systems, and for protection of imaging devices. The program is mainly experimental, with supporting theoretical work. Tests of nonlinear crystals also provide important information concerning carrier kinetics in semiconductors, through the difference frequency variation of  $\chi^{(3)}$ . In the past year, we have used this technique to determine carrier relaxation times, in the picosecond range, in n-Si : P and HgTe. Where appropriate, we investigate the device implications of optical-semiconductor interactions. Our studies of free carrier, spin-induced Faraday rotation, were motivated by the possibility of using this effect in tunable IR filters and CO2 laser isolators.

UNCLASSIFIED REPORT

ABSTRACT: (U) Many aspects of signal processing and communication theory have proven to be limited by a lack of sufficient developments in the areas of probability theory and mathematical statistics. Our investigations attempted to overcome this deficiency by contributing both to the underlying theoretical basis of the area as well as to some applied aspects of the area, and we have obtained a large body of results. Some principal thrust areas of our research effort have been concerned with quantization theory, signal detection, and estimation theory. A brief topical overview of our research areas follows. Quantization - existence of optimal quantizers, convergence properties of sequences of quantizers, design of quantizers. Signal detection - effects of statistical dependence, relative efficiency between detectors, nonparametric detection, Estimation - effects of imperfect data, a general class of fidelity criteria leading to nonlinear estimators, convergence properties of sequences of estimators; and Additional areas - median filters; stability of differential equations with random coefficients; bandwidth properties of random processes; content resolution in local area computer networks; image compression; counterexamples.

UNCLASSIFIED REPORT

ABSTRACT: (U) This work addresses the general problems of formulating continuum models of a large class of dynamic frictional phenomena and of developing computation methods for analyzing these phenomena. Of particular interest are theories which can adequately predict stick slip motion, frictional damping in structural dynamics, and sliding resistance. This work is divided into three principal parts. In Part I, a large body of experimental and theoretical literature on friction is critically reviewed and interpreted as a basis for models of dynamic friction phenomena. In Part II, continuum models of interfaces are developed which simulate key interface properties identified in Part I. Variational principles for a class of dynamic friction problems are also established. In Part III, finite element models and numerical algorithms for analyzing dynamic friction are presented. Also, a dynamic stability analysis is presented in which it is established that stick slip motion can be associated with dynamic instability of the governing nonlinear system for certain ranges of slip velocity and coefficient of friction.

UNCLASSIFIED REPORT

ABSTRACT: (U) The general goal of this project has been to enhance the understanding of surface phenomena related to thermionic energy conversion (TEC), in particular, surface properties of electrode materials which have the potential of enhancing significantly the performance of practical devices for advanced mode TEC. A variety of surface analysis techniques has been devoted to study of clean surface properties of Lanthanum Boride single crystals. Investigations of residual gas interactions with low work function emitter surfaces has been directed toward the study of O<sub>2</sub> interactions with low work function single crystal faces of Lanthanum Boride. Measurements were made on both the clean and oxidized Lanthanum Boride surfaces using Auger electron spectroscopy (AES) and x-ray photoelectron spectroscopy (XPS) and quadrupole mass spectrometry (QMS) for analysis of the desorbing molecular species. The nature of the surface oxide species were correlated with thermal evaporation characteristics. The coadsorption of Zirconium and oxygen onto Tungsten causes a lowering of the work function of the (100) crystal plane from 4.7 to 2.6 eV. The resulting surface is remarkably stable and practical application as a cathode for fine-focused beam applications.

ABSTRACT: (U) The capability of this facility was rather limited in terms of line resolution, contact uniformity, fabrication yield, and versatility. Although much encouraging results have been demonstrated with the preliminary devices, the lack of an ion-milling machine has kept on-going research projects from achieving much more results expeditiously. Similarly, the lack of the Ion Milling Machine has kept the group from fabricating micron-width grooves, slots, gratings, ridge waveguide, etc., on LiNbO3 and GaAs substrates for robust coupling between the optical fibers and the devices being explored, and thus realization of integrated optic device modules. An Ion-Milling Machine has been purchased. A special laboratory compartment together with necessary electrical and wet-lab utilities were constructed for installation of the complete ion milling machine facility. The facility will be in full operation in the near future.

ABSTRACT: (U) It is shown that conditions based on level crossings and related quantities can ensure that a random sequence contains sinusoidal components. The results are first motivated by considerations of data-reduction in signal analysis, and then formulated precisely for stationary Gaussian sequences. An analogy is drawn with a characterization of the sine function in the nonrandom case. The problem dealt with in this paper derives from an important problem of modern technology: the signature problem. To understand the problem, consider the real life example of an operating automobile engine monitored by an electronic device which records the engine's vibration as an oscillating signal. This oscillating signal, regarded as a function of time characterizing the engine's operating condition, is called the engine's signature. The signature problem is generally to use the signature to tell whether the engine is functioning properly or malfunctioning, and to detect abnormalities such as cracks in the engine block and parts. Signature analysis is regularly performed on various sensitive parts of aircraft which may develop cracks or fractures as a result of metal fatigue.

ABSTRACT: (U) A system for investigating superconducting films with surface acoustic waves down to 4.3 millikelvin up to frequencies of 4 GHz and up to magnetic fields of 95 K Gauss has been ordered, received and assembled. A dilution refrigerator has been installed in a new laboratory. It has been tested in place down to 4.3 millikelvin. The refrigerator has a top loading probe with four interchangeable slugs which can be used for different millikelvin temperature experiments. Each slug has 13 electrical leads which can be connected at millikelvin temperatures. A superconducting magnet has been obtained which has been tested up to 95 K Gauss in conjunction with a helium lambda tip. All the parts for an automatic ultrasonic attenuation and velocity system in the frequency range of 10 MHz have been ordered and assembled. Parts for the submicron photolithography subsystem required to reproduce masks with linewidths of 0.3 u which will be used for making interdigital electrodes which will act as transducers to launch surface acoustic waves in the GHz range have been received and assembled.

ABSTRACT: (U) This report describes design of a database management system called MIDAS which stands for Management of Information for Design and Analysis of Systems. The system is designed to handle large matrix data of different types. A prototype system is first implemented. The system is re-designed to improve its efficiency. Capabilities of the system are described. It is evaluated in the engineering environment by solving systems of linear equations. The system is flexible; its buffer size, page size and number of pages can be changed. Variations of these parameters is studied and their effect on the system performance is evaluated. It is concluded that the application programs must be developed carefully to efficiently use a database management system. In addition, application programmer must be somewhat knowledgeable of the internal workings of the system.

ABSTRACT: (U) Surface acoustic wave attenuation (SAW) and electrical resistivity on In/InO films has been measured. On one film it was found that both vortex antivortex dipoles associated with a Kosterlitz Thouless transition and excess local resistivity associated with granularity of the film contribute to the energy absorption in the film. On another film, with a high sheet resistivity, a peak in attenuation is observed which may be associated with a metal insulator transition at the local level. A technique for determining average grain size in a granular superconductor has been proposed. Proximity acoustoelectric coupling to a granular Al superconducting film has been demonstrated. This technique may be used to determine the separation between two surfaces that are less than 1000A apart. Measurement on the Er(1-x)Ho(x)Rh484 alloy system have been completed. A theoretical relaxation expression has been derived and is being used to analyze the maxima that have been observed in the attenuation curves. Preliminary measurements of both the attenuation and velocity of longitudinal waves in a single crystal of URu2Si2 have been performed.

UNCLASSIFIED REPORT

ABSTRACT: (U) In a review of the assumptions underlying various theories of interacting continua, an important finding was that the notion of the mixture as a continuum in motion is inadmissible except in the case of no relative motion between the constituents. Liquefaction of soil is primarily associated with relative motion of soil and water. Finite element implementation of Biot's theory was studied in respect to effectiveness of the popular time integration schemes as well as spatial discretization for one and two-dimensional wave propagation. Results showed that the conventional time-domain integration procedures which are quite effective for single material problems are not reliable for saturated soils. The numerical results were found to be quite sensitive to the choice of time-domain integration parameters. Variational formulations of Biot's theory were developed to construct a basis for alternative finite element approaches. For nonlinear problems, incremental equations were developed and variational formulation attempted allowing only material nonlinearity. In saturated soils subjected to dynamic loads, depending upon permeability and pore geometry, a part of the water would possibly be trapped and move with the soil rather than relative to it. This mass coupling effect was

UNCLASSIFIED REPORT

ABSTRACT: (U) Experiments were carried out, over a period of two years, in an Adaptable-Wall wind tunnel configured for testing of airplane models at very large lift. The program was intended especially to demonstrate Proof of Concept for this type of wind tunnel, in which the simulated stream vector is inclined appreciably to the tunnel axis. The measured inner flow is matched to the computed, updated outer flow by an iterative process. Wall-adaptation controls in this tunnel are varied panels in the floor and ceiling of the working section and a variable-angle inlet nozzle. Velocity components are measured by a Laser-Doppler system using a fixed laser and movable optical components. The test model used in these experiments was a high-wing V/STOL configuration having full-span wing flaps with lower-surface blowing of their inboard portions. In all of the experiments reported here, the combination of angle of attack, flap setting, and flap blowing was such as to produce large flow deflection and severe wall interference in a conventional tunnel. The model configuration was always laterally symmetrical, and most runs were made under the assumption of symmetrical flow. The iterative procedure, based on measured control matrices, typically led to minimum matching-discrepancies (root-mean-square values) of about three percent of stream speed after about six iterations. It is estimated that this reflects residual

AD-A174 900

UNCLASSIFIED

PAGE 86 EVJ58L

errors at the model of about one percent of stream speed. It is concluded that these results constitute successful Proof of Concept. Suggestions are made regarding the directions of further development of this type of wind tunnel. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) One-dimensional unsteady calculations to study the spray ignition process were performed first for a monodisperse fuel-air spray in front of a planar heated wall and later for polydisperse single-component fuel sprays. The effect of different droplet heating models was investigated and it is found that at certain equivalence ratios ignition delay time and energies can be smaller in the heterogeneous case than in the limiting gaseous premixed case. Because of the critical dependency of ignition upon the distance of the heat source to the nearest droplet, spray ignition criteria are not precisely defined by fuel type, droplet size distribution and equivalence ratio but a range of ignition delay times and ignition energies is found due to the probabilistic effect of droplet ignition. For polydisperse sprays it was found that ignition can be well correlated with an equivalent monodisperse spray by using a mean diameter based on the total surface area of the spray and not the Sauter-mean-diameter. The experimental part of the program was designed to verify the theoretical spray ignition description and should help in understanding the physics and chemistry of the process. It focused on the importance of transport mechanisms on individual fuel droplet ignition.

UNCLASSIFIED REPORT

ABSTRACT: (U) Theories of mechanical behavior of saturated soils are reviewed. The discussion spans the classical approaches to quasi-static and dynamic response of deformable porous media as well as theories of mixtures and their application in geomechanics. Different approaches to description of motion of superposed continua, derivation of balance laws and development of constitutive relationships are compared. The notion of motion of the mixture as a single body is questioned. Alternative concepts of behavior of liquid-solid mixtures are considered. The role of thermodynamic principle in development of constitutive relationships is examined. Keywords: Balance laws; Constitutive relations; Consolidation; Flow through deformable porous media; Liquefaction; theories of mixtures.

ABSTRACT: (U) This paper extends a basic result in reliability theory. The author show that the S-shaped property of the reliability function holds when the states of the components are associated; the earlier stronger hypothesis of independence among component states is unnecessarily strong. Keywords: random variables. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) This research seeks to unify certain problems of distributed parameter control: model reduction, control, sensor/actuator selections/failure, and decentralized control. These topics are all related and are to be unified through the quadric performance metric with use of cost decomposition methods. The final research topic on model error estimation is required to make vernier adjustments after best models and controllers are developed, to absorb remaining modeling errors. During the period covered by the grant, 18 conference and journal research papers were written. Titles include: Computer Aided Design of Suboptimal LQG Controller, Cost Equivalent Realizations of Stochastic Processes, Component Cost Analysis of Large Scale Systems, Comments on Realizations and Reduction of Markovian Models for Nonstationary Data, and On the Selection of Controller Order for the Control of Linear Dynamic Systems.

DESCRIPTORS: (U) \*PARAMETRIC ANALYSIS, \*OPERATIONS RESEARCH, COMPUTER AIDED DESIGN, CONTROL, COST ANALYSIS, COSTS, DECENTRALIZATION, DECOMPOSITION, DISTRIBUTION, DYNAMICS, ERRORS, ESTIMATES, LINEAR SYSTEMS, MARKOV PROCESSES, PARAMETERS, REDUCTION, SELECTION, STOCHASTIC PROCESSES, SYNTHESIS, MATHEMATICAL MODELS

SUPPLEMENTARY NOTE: Pub. in Operator Theory: Advances and Applications, v18 p10-30 1986.

ABSTRACT: (U) An algorithm of Schur for Characterizing power series that are bounded in the unit circle is shown to have applications to a variety of problems in science and engineering. These include speech analysis and synthesis, inverse scattering, decoding of error-correcting codes, synthesis of digital filters, modeling of random signals, Padé approximation for linear systems, and zero location of polynomials. We also demonstrate an intimate relation between Schur's algorithm and the recently introduced concept of displacement structure, which is fundamental to the construction of efficient procedures for factorization, inversion and eigenanalysis of matrices. It also has meaningful links with the theory of operators close to Hermitian and close to unitary. (Reprints).

UNCLASSIFIED REPORT

ABSTRACT: (U) This report summarizes work done on the dynamics and control of flexible and articulated spacecraft. The combined dynamical effects of elasticity and a rotating reference frame have been explored for structure in a zero gravity environment. A simple yet general approach to modeling was developed, and applied to analyze the dynamics of a specific prototypical structure. The effects of energy dissipation were included and studied in depth for a model problem. Equilibria, bifurcations, and asymptotic stability were analyzed in some carefully chosen examples which capture the essential general features of nonlinear distributed parameter models of rotating elastic structures. Keywords: Classical mechanics; Rotating reference frames; Rotating elastic media.

UNCLASSIFIED REPORT

ABSTRACT: (U) Nonlinear filtering theory has been developed over the last few decades, largely, as an application of stochastic calculus. The theory (which will be referred to below as the conventional or stochastic calculus theory) has led to many important new advances in the subject and, indeed, given rise to problems of interest to stochastic calculus itself. When it comes to statistical applications, however, the approach based on stochastic calculus has many shortcomings which originate from the use of the Wiener process as a model for noise. This point has been recognized by many writers and has led to attempts to create a pathwise or robust version of the theory. This article presents a very brief outline of an alternative approach developed recently in collaboration with R.L. Karandikar. In this theory, the Wiener process is replaced by finitely additive (f.a.) Gaussian white noise in the filtering model in which we also assume the independence of signal and noise.

## UNCLASSIFIED REPORT

ABSTRACT: (U) This document first defines the model and introduce the notation the author uses in this paper. A site percolation process in  $Z$  sub  $d$  (here  $d > 0$  or  $= 2$ ) is a family of probability measures  $p$  sub  $p$ ,  $p$  epsilon  $(0, 1)$  together with a collection of random variables  $\epsilon_{\alpha}$ :  $Z$  sub  $d$  approx  $(0, 1)$  such that under  $p$  sub  $p$  the  $\epsilon_{\alpha}$ 's are independent and  $p$  sub  $p$  ( $\epsilon_{\alpha}(x) = 1 = p$ ). A site  $x$  is thought of being occupied (nonoccupied) if  $\epsilon_{\alpha}(x) = 1$  ( $\epsilon_{\alpha}(x) = 0$ ). We say that  $x$  is connected to  $y$  if there is a path of occupied sites connecting  $x$  and  $y$ ; i.e. there is a sequence of sites  $x$  sub  $0 = x$ ,  $x$  sub  $1$ ,  $x$  sub  $2$ , ...,  $x$  sub  $n = y$  in  $Z$  sub  $d$  so that  $x$  sub  $i$  and  $x$  sub  $i + 1$  are nearest neighbors and  $\epsilon_{\alpha}(x$  sub  $i) = 1$  for every  $i = 0, 1, 2, \dots, n$ . We denote this event by  $(x$  approaches limit of  $y)$ . Let  $C$  sub  $0 = \{ \alpha : 0 \text{ approaches limit of } x \}$ . We say that  $C$  sub  $0$  is the cluster containing  $0$ .

## UNCLASSIFIED REPORT

ABSTRACT: (U) Optical computing has been effective at solving computationally difficult problems. Optical computing research has high risk, but high potential benefits. AFOSR has had the lead role in basic optical computing research and must continue this role in coordination with other government and industrial funding. Current and future optical computing systems can be organized into a unified structure with five major components: input, processor array, interconnections, memory, output. Optics has great potential advantages in speed, bandwidth and parallelism, but electronics has the advantages of a well-developed technology. Basic research needs: -Materials - nonlinear, synthetic structures, processing element arrays - SMLs, interconnections/ memories - materials, devices, arrays, architectures/ algorithms - utilize parallelism.

ABSTRACT: (U) Relativistic plane-wave Born-approximation  
calculations of cross sections for N shell ionization of  
Bi 83 and U 92 by protons with incident energies from 0.  
02 to 5 Mev are reported. The calculations were carried  
out by using Dirac-Hartree-Slater wave functions. Binding  
energy change and Coulomb deflection were taken into  
account. The relativistic cross sections are compared  
with values from nonrelativistic Hartree-Slater wave  
functions to study the effects of relativity. A test  
calculation with hydrogenic wave functions yields very  
different results. The only available measurements (for W  
74), revised with a corrected 4 d fluorescence yield,  
agree with present theoretical predictions for  $E_{sub 1} <$   
or = 0.1 Mev but fall below theory by a factor of 6 above  
 $E_{sub 1} = 0.4$  Mev. This glaring discrepancy invites  
further investigation. Keywords: Atomic physics;  
Ionization; Reprints.

UNCLASSIFIED REPORT

ABSTRACT: (U) An investigation of the power of the Euler equations in the prediction of conical separated flows is presented. These equations are solved numerically for the highly vortical supersonic flow about circular and elliptic cones. Two sources of vorticity are studied; the first is the flow field shock system and the second is the vorticity shed into the flow field from a separating boundary layer. Both sources of vorticity are found to produce separation and vortices. In the case of shed (i.e., separation point) is determined empirically. Solutions obtained with both sources of vorticity are studied in detail, compared with each other, and with potential calculations and experimental data.

ABSTRACT: (U) The overall objective of this proposal is to investigate the robustness to departures from independence of methods currently in use in reliability studies when competing failure modes or competing causes of failure associated with a single mode are present in a series system. The first specific aim is to examine the error one makes in modeling a series system by a model which assumes statistically independent component lifetimes when in fact the component lifetimes follow some multivariate distribution. The second specific aim is to assess the effects of the independence assumption on the error in estimating component parameters from life tests on series systems. In both cases, estimates of such errors will be determined via mathematical analysis and computer simulations for several prominent multivariate distributions. A graphical display of the errors for representative distributions will be made available to researchers who wish to assess the possible erroneous assumption of independent competing risks. A third aim is to tighten the bounds on estimates of component reliability when the risks belong to a general dependence class of distributions (for example, positive quadrant dependence, positive regression dependence, etc.).

UNCLASSIFIED REPORT

ABSTRACT: (U) The regular (RR) to Mach reflection (MR) transition boundary in pseudostationary flow in air was investigated, with emphasis on the influence of the shock induced boundary layer. Nearly 100 experiments were conducted in the RR to MR transition line over a range of incident shock wave Mach number  $1.1 \leq M_s < 6.5$  by conducting experiments in hypervelocity shock tube. The wedge angles used were 42, 45, 47, and 48 deg. Initial pressures were kept as low to maximize viscous effects and ranged from 0.4 kPa to 100 kPa. A comparison was made between the boundary layer thickness, and the deviation of the transition boundary from inviscid theory. This difference is called the von Neumann paradox. The von Neumann paradox is due to viscous effects. The deviation of the RR to MR transition line from the detachment criterion boundary was found to increase with a drop in initial pressure. The effect of the end was boundary layer on the RR to MR transition line was more pronounced at low Mach number ( $M_s < 2$ ), and a model is proposed to explain this behavior. Initial pressure was also found to influence the height of the Mach stem in MR. Lower

Initial pressure (with greater viscous effects) reduced the height of the Mach stem, which was found to be smaller than the inviscid prediction in all MR experiments. An explanation for the reduction in Mach stem height is suggested, but the causes was not thoroughly investigated. (Canada)

ABSTRACT: (U) MITHRAS is a coordinated multiradar program to study the upper atmosphere. Its purpose is to examine the interactions among the magnetosphere, ionosphere, and thermosphere, as well as the phenomena that result from these interactions. It is based around a data set acquired by the Chatanika, Millstone Hill, and EISCAT Incoherent-scatter radars between May 1981 and June 1982. A larger portion of this period was unique because it was the only time that three radars, well separated in local and magnetic time, operated together to probe the high-latitude region. The period was also unique because it coincided closely with solar maximum and the DE-2 spacecraft was available for correlative observations. To learn as much as possible from the observations, several tools were developed to improve the handling and analysis: a data-exchange tape format was developed, new display methods using color were implemented to present the data, F-region analysis procedures were extended, and binning procedures were developed to facilitate statistical analysis of the data. In addition, workshops were held so that the observations could be discussed and interpreted by the MITHRAS participants.

UNCLASSIFIED REPORT

ABSTRACT: (U) A develop a computational method is  
developed for the estimation of parameters in a  
distributed model for a flexible structure. The structure  
we consider (part of the 'RPL experiment') consists of a  
cantilevered beam with a thruster and linear  
accelerometer at the free end. The thruster is fed by a  
pressurized hose whose horizontal motion effects the  
transverse vibration of the beam. The Euler-Bernoulli  
theory is used to model the vibration of the beam and  
treat the hose thruster assembly as a lumped or point  
mass dashpot spring system at the tip. Measurements of  
linear acceleration at the tip are used to estimate the  
hose parameters (mass, stiffness, damping) and a Voigt-  
Kelvin viscoelastic structural damping parameter for the  
beam using a least squares fit to the data. Spline based  
approximations are considered to the hybrid (coupled  
ordinary and partial differential equations) systems;  
theoretical convergence results and numerical studies  
with both simulation and actual experimental data  
obtained from the structure are presented and discussed.

ABSTRACT: (U) The stability of digital ladder filters related to LC Cauer ladder low-pass filters by Bruton's LDI transformation is studied. Necessary and sufficient conditions for the digital LDI Cauer filter to be lossless and for a corresponding doubly terminated filter to be stable are derived. A concurrence relation between the stability and sampling rate requirements is shown for implementations by switched capacitors, by which appropriate sampling rate generally guarantee also the sufficiency condition for stability. Keywords include: Digital ladder filters, LC Cauer ladder, Low-pass filters, LDI transformation. (Reprints)

ABSTRACT: (U) It has been demonstrated that small single-turn printed loops can be used as sensors with sufficient sensitivity to be useful in NDE and robotics and that printed-circuit techniques facilitate the fabrication of arrays of small loops to provide electronic scanning with high spatial resolution. It has also been shown that deconvolution techniques improve the spatial resolution of such sensors in detecting edges and slots. Future research plans under this contract include developing a model for inductive sensor arrays; designing and building a horizontal-loop array with vertical connections; demonstrating electronic scanning in one, and perhaps two, dimension; and exploring the possibilities of arraying drivers as well as sensors.

ABSTRACT: (U) This paper considers a tracking problem  
for a linear system with uncertain parameters. The  
objective is to design a state feedback controller so that  
for all allowable parameter values, the system internally  
stable and its output asymptotically tracks the command  
reference input. A controller having this property is  
termed a robust tracking controller. Conditions are given  
which can be used to design a robust tracking controller.  
The controller is linear with readily computable gains.  
The results are illustrated with an example. Keywords:  
Reprints; Uncertain systems; tracking; linear control  
problems.

ABSTRACT: (U) In this preliminary investigation of an  
aeroelastically-induced constrained warping phenomenon  
for a composite (supermaneuverable type) aircraft wing,  
the wing is analytically modelled as a straight flat  
laminated plate using various forms of highly simplified  
aerodynamic loads. The free vibrations and (stability  
importance aspects are examined to obtain physical  
insights and determine their importance and/or design  
implications. An affine transformation concept and a non-  
dimensionalization scheme were used and an evolution of  
effective warping parameters with which to study this  
phenomenon was performed. The virtual work theorem and  
variational principles were used to derive the equations  
of motion based on the assumed wing displacements. Closed  
form solutions to the uncoupled versions of these  
equations were examined with the following results: 1)  
Incorrect modelling of the warping phenomenon can lead  
to errors in excess of 80% for the analytically predicted  
aeroelastic characteristics of composite aircraft wings;  
2) accurate modelling of the warping phenomenon is  
particularly important for wings with mass coupling or  
elastic coupling (e.g., wings aeroelastically tailored

using elastic coupling) and for higher vibration modes; 3) neglect of the warping constraint can result in either under- or overpredicted analytical results and lead to incorrect identification of aeroelastic divergence modes. The existence of closed-form free vibrations solutions for composite wings with elastic coupling and constraint of warping was established.

UNCLASSIFIED REPORT

ABSTRACT: (U) Two layer thermal barrier coatings are currently being developed for extending the performance of nickel base superalloy gas turbine engines. The best materials reported to date comprise a Ni-Cr-Al-Y bond coat and a Y2O3 partially stabilized ZrO2 (Y-PSZ) thermal barrier coat. The Y level of both the bond coat and the thermal barrier coat have been studied empirically but the fundamental factors that govern optimization of the thermal barrier system are not well understood. Optimized systems perform remarkably well during high temperature exposure and thermal cycling but failure still tends to occur by radial cracking in the ceramic coat and circumferential cracking at the various metal/ceramic interfaces. Two fundamental aspects of the behavior are discussed: firstly, phase stability in the zirconia-yttria system itself, particularly the desirable tetragonal phase, and secondly, the nature of the important zirconia-alumina interface which forms during oxidation of the underlying bond coat. The results of this research are described briefly below and in the various appendices.

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper presents a geometric analysis of bifurcations leading to chaos for Hamiltonian systems with two degrees of freedom of the form  $\dot{x} = y$ ,  $\dot{y} = -\text{gradient } V(x)$ . Two bifurcation parameters are considered. One is the energy level and the other is an angle,  $\psi$ , between two homoclinic orbits. Though global non-linearities are necessary, the results are obtained by local analysis of the flow near the origin where it is assumed that  $(D^2V)(0) = I$ , the  $2 \times 2$  identity matrix. For a fixed energy level it is shown that as  $\psi$  decreases through  $90^\circ$  the two homoclinic orbits bifurcate into two homoclinic orbits, a periodic orbit, and connecting orbits. These orbits can then be used to define a compact region in  $R^4$ . Now treating the energy as a parameter the trajectory of orbits passing through this compact region can be described using symbolic dynamics. In this case it is shown that a single periodic orbit bifurcates into three periodic orbits whose stable and unstable manifold intersect transversely.

ABSTRACT: (U) Distributional properties of the treatment assignment variables  $T$  sub  $1, \dots, T$  sub  $n$  under Efron's (1971) biased coin design are derived. These properties are conditional on the terminal imbalance of the treatment allocation. Recursive procedures are presented for obtaining the conditional moments of  $T$  sub  $1, \dots, T$  sub  $n$ . Based on these results, large-sample test statistics are proposed for the randomization test of the null hypothesis of no treatment difference. In contrast to Efron's test statistic, the approximations herein proposed are applicable when there is a treatment allocation imbalance. Keywords: markov chains; chemical tests; conditional means and covariances; computerized simulation.

ABSTRACT: (U) The initial objective of this project was to investigate the relation between the temporal filtering properties of visual neurons and the performance of human observers when they view intermittent visual displays, e. g. video screens. The scope of the project was reduced by the support level set by AFOSR to focus just on human observers and to omit any experiments on neurons in experimental animals. Specific aims of the project initially included the design and fabrication of a variable-raster-rate electro-optic display, and the use of this novel device to measure the contrast sensitivity function at different raster rates. These two specific aims have been reached and are described in the full report.

ABSTRACT: (U) Laser Science is an emerging technical area with a strong interdisciplinary flavor. It is based on atomic and molecular physics, chemical physics, condensed matter physics, optical physics and engineering, plasma physics, physical chemistry, photochemistry, materials science and engineering, electrical engineering, gaseous electronics, quantum electronics, and electro-optics. At the core of laser science are the mechanisms of the lasers themselves and the interaction of the laser photons with matter (spectroscopy and photoprocesses). Surrounding this core is the wide spectrum of scientific applications of lasers, not only in the disciplines mentioned above, but also in virtually every other area of science and technology. The primary purpose of the conference is to survey annually both the laser and spectroscopy/photoprocesses core areas and a wide variety of selected scientific applications of lasers.

ABSTRACT: (U) In turbulent combustion, mixing by molecular transport is an essential process that is not well understood. Because mixing occurs on the smallest length and time scales it is difficult to study experimentally. Instead, we are starting a study based on the direct numerical simulation of turbulence, initially for a conserved passive scalar in homogeneous isotropic turbulence. The Eulerian velocity and scalar fields are calculated from the exact evolution equations, and both Eulerian and Lagrangian statistics are deduced from the computed fields. A particle tracking scheme, need to extract Lagrangian information, has been implemented and is undergoing testing. In addition, in order to study processes in stationary turbulence, a forcing algorithm has been developed and implemented, and is being tested.

ABSTRACT: (U) Results of the data analysis employing data collected during the NGENDEI Seismic Experiment in the southwest Pacific Ocean are presented. This experiment tested the DARPA Marine Seismic System (MSS) and verified the improved signal-to-noise ratio achieved by burying the instrument within the oceanic crust. Generally, all the goals of the experiment were achieved. The experiment, which took place on the Deep Sea Drilling Project Leg 91, was designed to test the MSS in a realistic environment near an active submarine trench. The Scripps's ship, the R/V Melville, was used in addition to the D/V Glomar Challenger for tasks related to site surveying, ocean bottom seismograph (OBS) deployment and refraction shooting. Deployment of an autonomous recording package on the seafloor was successful. The OBS's launched several times during the course of the experiment operated correctly in all instances including the 45 day teleseismic recording phase at the end. The MSS recording packages as well as the six OBS's were recovered at the end of the experiment. The MSS was left in the borehole and the coaxial cable was terminated in a dummy load. The mooring system used for recovery was redeployed in the event a future experiment became necessary or desirable.

ABSTRACT: (U) Measurements of energy- and angle-resolved  
 distributions of neutral atoms desorbed from ion-  
 bombarded single crystals are obtained using a novel  
 multiphoton resonance ionization scheme. Experimental  
 results are compared successfully to molecular dynamics  
 calculations of the ion/solid collision event. This  
 comparison suggests that the distributions from Rh (111)  
 are sensitive to the crystal structure of the top atomic  
 layer. Calculated distributions match experimental ones  
 when oxygen atoms are assumed to adsorb in 3-fold hollow  
 (c-site) bonding configurations.

## UNCLASSIFIED REPORT

ABSTRACT: (U) The physics of some problems that arise in  
 impinging jet flows have been investigated using a Very  
 Large Eddy Simulation (VLES) of the Navier Stokes  
 equations. The problems that have been examined include  
 the upwash fountain covered by the collision of two  
 wall jets, possible causes of a Reynolds number scaling in  
 the suck down phenomena and possible flow resonance. The  
 effects of heat were also studied. It was found that the  
 VLES technique can help explain certain aspects of jet  
 flows. Keywords: Jet Flows; Turbulence.

UNCLASSIFIED REPORT

ABSTRACT: (U) Groups of male and female Fischer 344 rats, C-57-BL mice and Syrian Golden hamsters were dosed with 5-hydroxy-JP-10 and 5-keto-JP-10, the metabolites of the cruise missile fuel JP-10, in order to study their toxicity. 5-Hydroxy-JP-10 proved to be an extremely toxic central nervous system depressant. The effects of 5-hydroxy-JP-10 on weight gain appeared to be most pronounced in the male rat. 5-keto-JP-10, because it is absorbed less readily than 5-hydroxy-JP-10, appeared to be relatively non-toxic. Neither of the JP-10 metabolites produced nephrotoxic effects in the doses administered.

ABSTRACT: (U) This report summarizes the current status of a combined experimental and theoretical investigation of the response of multiphase porous media to dynamic loading. This completes the first year of a planned three year investigation. Under the experimental portion, laboratory test were devised and conducted to measure the compressibility of soil and rock grains containing a large percentage of microporosity. Test were also developed to model liquefaction due to uniaxial strain loadings and to measure the amount of late-time consolidation as a function of the loading parameters. Finally, a test apparatus to measure fluid friction and energy absorption in porous media under specified flow conditions, including laminar, transient, and turbulent, was designed and constructed. This is currently undergoing evaluation. Under the theoretical portion of the work, derivations and computational algorithms to model the response of saturated soils and rocks to uniaxial and hydrostatic compressional loads were developed. The general purpose two-phase code TPDAPII was completely revised to include more realistic plastic and elasto-plastic material models and more efficient

ABSTRACT: (U) In a logistic regression model when covariates are subject to measurement error the naive estimator, obtained by regressing on the observed covariates, is asymptotically biased. This reprint introduces a bias-adjusted estimator and two estimators appropriate for normally distributed measurement errors - a functional maximum likelihood estimator and an estimator which exploits the consequences of sufficiency. The four proposals are studied asymptotically under conditions which are appropriate when the measurement error is small. A small Monte Carlo study illustrates the superiority of the measurement-error estimators in certain situations.

UNCLASSIFIED REPORT

ABSTRACT: (U) This document gives sufficient conditions for local continuity of the isonormal process  $L$  at some point of its parameter set. Since a Gaussian process, defined on a compact parameter space, that is a.s. continuous at each point is sample continuous, the result can be applied to the problem of general sample continuity of Gaussian processes. It is shown that sufficient conditions are strictly weaker than the classical sufficient conditions for sample continuity.

ABSTRACT: (U) This is a final report of scientific achievements and activities sponsored by U.S. Air Force Office of Scientific Research under contract AFOSR 80-0170 as of July 31, 1985. Research activities have been concentrated on two main areas: Design of experiments and Reliability. Research on design of experiments relates directly to problems of data collection and analysis relevant to virtually all scientific experiments. There is a strong need in the Air Force to reduce costs and save time in the collection and analysis of large amounts of data, such as communication, engineering, equipment testing, and aerospace medicine data. The reduction in costs and time should be done clearly without any damage to the statistical quality of the data being collected and analyzed. The research problems not only add to our store of knowledge about the multiple facets of data collection and data analysis in general, but these have immediate applications to many important problems with which the United States Air Force is faced. The main research emphasis has been to obtain designs which are efficient, easily applicable and yet meet the budgetary constraints.

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper demonstrates severe problems in some instances with using an unconstrained algorithm to estimate the parameter  $q$ . When modified, either by regularizing the problem using Tikhonov regularization or by constraining the estimate set the algorithm does give good estimates. Unlike the unconstrained algorithm, both the Tikhonov and constrained algorithms are stable with respect to increasing  $M$  while holding  $N$  fixed. However as  $N$  is increased the estimates from the Tikhonov algorithm do not improve as much as do those of the constrained algorithm. The Tikhonov estimates are biased by the regularization of the cost functional, and never show all the detail of  $q$  when  $q$  has significant variation. Both the constrained and Tikhonov estimation algorithms are stable with respect to systematic errors in the input data, while, except when  $N$  is large, the unconstrained algorithm fails to give good results on even the exact data. For both the Tikhonov and constrained algorithms there are parameters which affect the algorithm's performance. For the constrained algorithm suitable constraints must be found while for the Tikhonov algorithm suitable values of  $a$  and  $b$  must be found. The constrained algorithm has the advantage that the constraints used here, i.e. limits on the slope of  $q$ , have an obvious meaning, and so may well be known in

UNCLASSIFIED

DTIC REPORT BIBLIOGRAPHY SEARCH CONTROL NO. EVJ58L

advance. In the Tikhonov algorithm b and a have no obvious meaning. They must be suggested by looking at the change in the estimate behavior as b and a change, and perhaps using some apriori knowledge about the shape of q to choose values of b and a that give an estimate that is neither too flat, nor too oscillatory.

## UNCLASSIFIED REPORT

ABSTRACT: (U) The results of earlier calculations of the quality factor of the piezoelectric thin film on semiconductor composite resonator due to radiation into the semiconductor wafer for the strip case both when trapping is and is not present are briefly discussed. Experimental verification of the results is noted. It is also noted that the direct calculation procedure is extremely cumbersome to use, but that it is required to check the accuracy of a perturbation procedure which is much easier to use. The perturbation procedure for the calculation of the quality factor of the composite resonator due to radiation into the semiconductor wafer is discussed and it is noted that the perturbation procedure enables calculations for the case of rectangular electrodes and diaphragms to be performed. It is further noted that for the strip case the calculations of the quality factor using the perturbation procedure are in good agreement with the results obtained from the earlier more cumbersome direct procedure. Keywords include: Piezoelectricity; Elasticity; Resonators; Bulk Waves; Thin Films; Semiconductor Wafers; Composite Resonators; Energy Trapping; Radiation; Quality Factor; Plate Vibrations.

ABSTRACT: (U) Research was completed on a program to understand the mechanisms by which mildly relativistic electron beams can generate microwave radiation when injected into plasmas. The chief phenomena found to be involved were (1) stimulation of Compton conversion of Langmuir waves excited by relativistic beams and (2) multiple Raman up conversion of radiation from pre-existing Langmuir turbulence. Numerical programs were developed for computing the evolution of beam excited Langmuir waves into strongly turbulent states. It was further experimentally determined that quiet plasmas with low level of ambient density fluctuations were necessary in order to obtain optimum radiation.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in Geochimica et Cosmochimica  
Acta, v50 p1545-1548 1986.

ABSTRACT: (U) The hydrocarbon solution process in water was studied because it is important in environmental and geological situations. The aqueous solubility of binary hydrocarbon mixtures was determined (n-octane + 1-methylnaphthalene at 20 and 70 C; n-octane + ethylbenzene at 20 C and tetraline + methylcyclohexane at 20 C). Vapor-liquid equilibrium hydrocarbon phase activity coefficients for the above mixtures were also determined. Hydrocarbon activity coefficients in the aqueous phase were found not to be measurably reduced in the presence of hydrocarbon co-solutes. This indicates that the effects of aqueous phase solute-solute interactions can not be determined within the precision of water solubility measurements. The presence of a substantial amount of water in the liquid hydrocarbon phase at 70C did not significantly affect the hydrocarbon activity coefficients in the hydrocarbon phase. Activity coefficients estimated by the UNIFAC group-contribution method indicate that water in the hydrocarbon phase may not significantly affect hydrocarbon phase activity coefficients up to 150 C.

ABSTRACT: (U) It is shown that a symmetry in an optimization problem induces a decomposition of the optimal feedback control law into factors. One factor can be calculated algebraically and depends only on the symmetry; the other factor corresponds to a lower dimensional optimization problem. This gives a priori information about the structure of the optimal feedback control law and indicates a possible more efficient method for optimizing such systems. UNCLASSIFIED REPORT

ABSTRACT: (U) This report describes theoretical and experimental study of dense sprays. The work was divided into two phases: (1) an investigation of particle laden water jets; and (2) an investigation of large scale liquid jet in the atomization regime. The particle laden jet experiments involved nearly monodisperse glass particles in water injected into still water, to simulate phase density ratios typical of high pressure sprays. Preliminary findings suggest that the locally homogeneous flow approximation, where interphase transport rates are assumed to be infinitely fast, is more successful for this flow than was observed during earlier work with phase density ratios further from unity. This is encouraging for application of relatively simple locally homogeneous flow analysis to high-pressure combustion processes encountered in power and propulsion systems. Measurements of the atomization of the atomization of large scale liquid jets show the presence of an all liquid core which extends an appreciable distance from the injector (ca. 200 injector diameters) at atmospheric pressure conditions. The drop containing shear layer adjacent to this core exhibits some properties of a locally homogeneous flow, however, large drops were also formed at the liquid surface which probably depart from this behavior. Measurements of liquid volume fraction suggest relatively slow rates of turbulent mixing for the

Presented at the Structures, Materials and Dynamics  
Conference (24th), 14-16 May 84.

ABSTRACT: (U) The transient response of lattice truss  
plates is studied with emphasis on how the individual  
lattice members dynamic characteristics influence with  
transient response characteristics. When the lattice  
members are modeled as bars, the transient responses are  
dominated by the low frequency components that correspond  
to the continuum thick plate case. However, when the  
lattice members are modeled as slender beams to be more  
realistic, the dynamic characteristics of the individual  
lattice members significantly influence the global  
transient response. The level of influence increases as  
the member slenderness ratio increases. The results  
underscore the importance of local high wave number modes  
that must be treated satisfactorily both in passive and  
active control of large lattice truss space structures.

EVJ58L

UNCLASSIFIED REPORT

ABSTRACT: (U) This work has been directed toward investigations of fundamental aerothermal phenomena in hypersonic flow, with particular emphasis on viscous/inviscid interaction phenomena. The experimental studies were conducted to examine the changes in the structure at the base of a hypersonic turbulent boundary layer as it is subjected to a strong self induced pressure gradient in regions of shock wave/boundary layer interaction. The initial phase of the theoretical program was directed toward summarizing existing techniques for obtaining Navier/Stokes solutions for laminar flow over flat plates in hypersonic flow. In the experimental program, surface and flow field measurements were made to examine the detailed flow mechanics associated with turbulent boundary layer separation over a large cone flare model at Mach 11, 13, and 16 for Reynold numbers up to 100 million. Solutions have been obtained to Navier-Stokes equations for the laminar flow over the leading edge of a sharp flat plate in Mach 16 flow for highly cooled wall conditions using a modified McCormack/Shang fully explicit formulation. To obtain a stable converged solution it was necessary to reduce the grid size close to the leading edge to the order of the mean free path, and typically 20,000 time steps were required to achieve convergence. However, once obtained, the solution was a

ABSTRACT: (U) Theoretical and experimental work on the deformation and fracture of fibrous composites with distributed damage is described. Emphasis is on establishing the existence of potentials analogous to strain energy and on using these so-called work potentials in fracture studies. The difference between changing damage and constant damage processes is accounted for by using multivalued work potentials. It was shown previously that these potentials lead to a path independent  $J$  integral for characterizing fracture. A recent study is described in which the  $J$  integral is used to determine fracture energy for delamination in double-cantilevered beam specimens with a large percentage of off-axis fibers; the results are compared with fracture energies found by standard methods (which to not account for effects of distributed damage). Discussed next are investigations of flat rectangular bar specimens and thin-walled tubes under axial and torsional loading. The limited amount of experimental data presently available on angle-ply laminates confirms the existence of a potential even when there are large increases in

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper investigates robust optimum invariant tests of some covariance structures that naturally arise in the context of robustness study in linear models. To describe this concept, let  $(Y, X \text{ beta}, \text{sigma sq I})$  be the assumed (probably incorrect) model while  $(Y, X \text{ beta}, \text{sigma sq V})$  be the correct model, resulting in the specification error in the dispersion matrix. Then it is well known that the BLUEs of all estimable linear parametric function A beta remain the same under both the models if and only if the following condition holds on the structure of V:  $LX'VZ = 0$  where Z denotes a matrix of maximal rank satisfying the condition  $Z'X = 0$ . Our object is to test the null hypothesis that V possesses the structure based on samples on Y under the model  $(Y, X \text{ beta}, \text{sigma sq V})$  for a fixed design matrix X. This hypothesis is of considerable interest as its acceptance greatly simplifies determination of BLUEs of estimable linear parametric functions.

UNCLASSIFIED REPORT

ABSTRACT: (U) A system of real time collision avoidance was implemented. The system is based on the use of potential functions around obstacles. An experimental manipulator programming system COSMOS using the method has been designed for the PUMA and demonstrated with obstacles detected by an MIC vision module. A dynamic simulator was implemented as a software equivalent of a robot arm. A new nonlinear and generalizable technique has been developed that will continually monitor the parameters of a robot arm to estimate continuously the inertial forces and friction in robot joints.

Contributions have been made toward the successor for ACRONYM the modeling system of successor is greatly generalized to include multiple naming, holes and set operations on volumes. Automatic Task Level Assembly Synthesizer (ATLAS) was advanced significantly in power and usability. Several portable versions of LISP have been developed & both utilized. Implementation of new edge operator, tests of shape from a shading algorithm, and experimentation toward building an active ranging device.

ABSTRACT: (U) In Task I, the research primarily involved  
refinement of the experimental apparatus, instrumental  
measurement techniques, and acquisition of experimental  
data. Special efforts were made to assure the reliability  
of the measurements, including runs made to examine the  
process of oxide formation when using pure nickel  
surfaces. Experimental data were acquired for both liquid  
kerosene (Jet-A) and gaseous commercial propane fuels  
over a broad range of run conditions. Evaluation of the  
results in the context of existing theories and  
modifications of the CONCHAS-SPRAY code to model this  
experimental system were also undertaken. In Task II, the  
extensive experimental results on blowoff velocity,  
obtained using both conventional Vee-gutter and single-  
sided flameholders, provided the data base for an  
analytical study of the factors governing the stability  
characteristics of bluff-body flameholders. An equation  
was derived for predicting blowoff velocity in terms of  
flameholder size, flameholder blockage, ambient air

pressure and temperature, and laminar flame speed. Predictions of blowoff velocity based on this equation showed excellent agreement with experimental values. In Task III, experimental studies were completed and results correlated for ventilation flow from surroundings into a cavity with a small internal flow. Extensive flow visualization studies were also undertaken for flow past a protrusion, including the case of a jet through the protrusion. These studies provided data on formation of vortices adjoining and over the protruberance and the nature of jet flow entrainment into them.

ABSTRACT: (U) Practical and theoretical considerations in computing first passage time statistics are considered. We are motivated by first passage times as models of failure times. In Section 1, the relevance of first passage time distributions as failure time models is indicated. Also, the spectral series expansion solution to the backward equation is introduced. In Section 2, algorithms for approximating  $w(x,t)$  are obtained. In particular, the infinite spectral expansion of  $w(x,t)$  is approximated by an  $n$ -term sub-expansion which matches the first  $n-1$  moments. Proofs validating the spectral expansion and the related approximation scheme are given in the Appendix. In Sections 3 and 4, methods are given for obtaining the eigenvalues and first passage moments, necessary for computing approximations to  $w(x,t)$ . In Section 5, computational issues related to calculating the moment generating function are considered. Sections 6 and 7 include theoretical complements about first passage times. In particular, the moment generating function is shown to possess an interesting representation having exponential form (cf equations (7.1)). This exponential representation is related to asymptotic expansions used in analyzing perturbations of certain second-order differential equations.

ABSTRACT: (U) The main objectives of this research have been the development of smooth nonparametric estimators of quantile functions from right-censored data and the further study of smooth density estimators from censored observations. In particular, kernel-type quantile estimators have been obtained under censoring which give better estimates of percentiles of the lifetime distribution than the usual product-limit quantile estimator. During the past year, asymptotic properties of these kernel quantile estimators have been developed, including asymptotic normality, consistency, and mean square convergence. In addition, a data-based procedure for selecting the bandwidth has been investigated using the bootstrap, and approximate confidence for the true quantile have been proposed using bootstrap estimates of the sampling distribution. Theoretical results on the optimal bandwidth selection for kernel density estimators under random right censorship have also been obtained. New results in several other problem areas were also developed. These included the study of linear empirical Bayes estimators, prediction intervals for the inverse Gaussian distribution, nonparametric hazard rate estimation under censoring, nonparametric inference for step-stress accelerated life tests under censoring, discrete failure models, simultaneous confidence

ABSTRACT: (U) This document considers a single-input nonlinear discrete-time system of a certain form. Many authors have studied (local or global) linearization (Cheng et. al. 1985, Hunt and Su 1981, Jakubczyk and Respondek 1980, Krener 1973, Su 1982) and approximate linearization (Krener 1984) by state feedback and coordinate change for nonlinear continuous-time systems. This paper discusses necessary conditions and sufficient conditions for local linearization and approximate linearization by state feedback and coordinate change for nonlinear discrete-time systems. Other related work on nonlinear discrete-time systems can be found in (Grizzle 1985a, 1985b, Grizzle and Nijmeijer 1985, Monaco and Normand-Cyrot 1983a, 1983b). Keywords: Matrices(Mathematics).

ABSTRACT: (U) Work was carried out on high density (16 to 64 Mbit/sq cm) magnetic bubble device technology. Highlights of the research include the successful fabrication of silicon MOSFETS on bubble garnet substrates and the development of ion implanted bubble devices utilizing 0.5um bubbles in garnets with isotropic magnetostriiction. In addition, studies of the effects of ion implantation on garnet lead to improved fabrication techniques for the 0.5um devices. Chips utilizing 1um bubbles were demonstrated to have about 8% bias field margins at 50 Oe drive, and a numerical model was developed to model current accessed ion implanted devices. Keywords Include: Bubble Memory, Ion Implantation, Garnet, Silicon-on-Insulator, and Silicon-on-Garnet.

# UNCLASSIFIED REPORT

ABSTRACT: (U) During the past two years, we have been able to understand, in principle, the mechanism of one predominant mode of combustion instability in dump combustors for ramjet engines. The objectives of further experiments have been to provide a quantitative, physical basis for elements of this mechanism which will allow application of the results to a wide class of combustor sizes, fuels and mixture ratios, and to more complex acoustic environments. One mode of unsteady combustion in dump burners, which under certain circumstances may lead to combustion instability, involves the periodic formation of a large vortex in the separated shear layer and its subsequent movement toward the combustor wall. When oscillations appear, the frequency of the vortex shedding coincides with that of some natural acoustic mode of the apparatus. Detailed experiments show that the heat release which drives the oscillation occurs predominantly as the result of an interaction between this vortex and the wall. Recent experiments and calculations have shown that the time delay between vortex formation and the wall encounter is strongly dependent on the pressure amplitude of the oscillation and, consequently, and acoustic mode of particular frequency will be excited to an amplitude required to produce the suitable phase of the heat release. Experiments have been performed to assess the role of

ABSTRACT: (U) Consider a single server first in first out queue in which each arriving task has to be completed within a certain period of time (its deadline); more precisely, each arriving task has its own deadline - a non-negative real number - and as soon as the response time of one task exceeds its deadline, the whole system is considered to have failed. (In that sense the deadline is hard.) The main practical motivation for analyzing such queues comes from the need to evaluate mathematically the reliability of computer systems working with real time constraints (space or aircraft systems for instance). The main concerns with the analytical characterization of the transient behavior of such a queue in order to determine the probability of meeting all hard deadlines during a finite period of time (the mission time). The probabilistic methods for analyzing such systems are suggested by earlier work on impatience in telecommunication systems. Keywords: queues with breakdown; real time systems; transient analysis; reprints.

UNCLASSIFIED REPORT

ABSTRACT: (U) The dynamic properties of two two dimensional lattice structures for large space structures were investigated both analytically, using the COSMIC NASTRAN finite element code, and experimentally, using an HP3451C Fourier analyzer, its accompanying modal analysis software, and a procedure called experimental modal analysis. One of the lattices was composed of five identical repeating substructures (5 bay beam). The other lattice was composed of twenty two identical repeating substructures (22 bay beam). For a frequency range extending from 0 Hz to 20 kHz, the NASTRAN analyses identified approximately 180 natural frequencies and mode shapes for each of the structures. The experimental modal analyses (limited by the frequency content of the impact excitation force) identified 34 mode shapes and natural frequencies of the 5-bay beam, and 18 mode shapes and 30 natural frequencies of the 22-bay beam. The COSMIC NASTRAN-predicted natural frequencies and the natural frequencies measured using experimental modal analyses agreed to within seven percent. The NASTRAN frequencies were consistently lower than those measured using the Fourier analyzer, probably because of inaccuracies in the finite element modeling of the intersections of the substructures. The Fourier analyzer also generated modal parameters (natural frequencies, damping ratios, and complex residues) for the two structures. In general,

ABSTRACT: (U) Coupled-cluster (CC) and many-body perturbation theory (MBPT) studies of the rhombic and linear structures of C<sub>4</sub> are reported. For each isomer, the electronic spectra is obtained, and comparisons are made with experimental matrix-isolated ESR and electronic spectra. The closed-shell superscript 1 A sub q rhombic ground state is found to be more stable than the superscript 3 sigma sub g(-) state of the linear isomer by 5 kcal/mol at the highest level of calculation performed (CCSDT-1). However, the predicted spectrum for linear C<sub>4</sub> is in reasonable agreement with the observed results. An allowed electronic transition for the rhombus is predicted to lie in the same region, suggesting the possibility that both isomers could coexist in the experiment. Finally, vibrational frequencies for the rhombic isomer are calculated using analytical second-order MBPT second derivatives to aid in the experimental identification of this transient species.

UNCLASSIFIED REPORT

ABSTRACT: (U) The research performed under this grant is concerned with distributed languages and algorithms. The results obtained can be divided into 5 major areas: Distributed Languages - High level Consideration; distributed algorithms; network communication; support of multicast; and computer program verification.

ABSTRACT: (U) The objective of this research is to investigate two promising systems as the basis for high temperature aluminum alloys useful to 425 C (800 F). The first is a metal matrix composite consisting of an aluminum-magnesium alloy matrix reinforced by spinel (magnesium aluminate) particulate. The second system is tri-aluminum (zirconium, vanadium) dispersed in aluminum matrix. Here the lattice parameter matches that of the matrix. Research on dilute alloys has shown a low coarsening rate for this intermetallic at 425 C. Study of more concentrated alloys with the necessary volume percent of dispersoid for high temperature creep and fatigue resistance is underway. A procedure for preparing specimens of the aluminum alloy matrix-spinel composite has been worked out and specimens are being prepared. In the procedure rapidly solidified alloy powder and oxide are mechanically alloyed, cold pressed, hot pressed, pressure forged and annealed. Extrusions containing 5 volume percent tri-aluminum (0.75 vanadium, 0.25 zirconium) were prepared for this research by Lockheed-Palo Alto from rapidly solidified foil. The measured creep rate at 425 C is much lower than in the current aluminum-iron-cerium alloy.

## UNCLASSIFIED REPORT

ABSTRACT: (U) In this report the dynamic behavior of metallic bodies subjected to dry frictional contacts is studied. A simple model of interface response which incorporates a constitutive equation for the normal deformability of the interface and the Coulomb law of friction is developed. This interface model is incorporated in the formulation of problems in continuum mechanics that involve the contact of linearly elastic or viscoelastic bodies. Variational formulations for these problems are established and existence and uniqueness results are proved for steady-sliding and dynamic frictionless or frictional contact problems. The same interface model is also incorporated in finite dimensional models for contact problems: a simple rigid body model and finite element space discretizations of the continuum models. Numerical studies steady sliding and its dynamic stability are presented, as well as numerical studies of friction-induced oscillations. In the latter case, the Newmark method and the central-difference technique are used to integrate numerically the equations of motion. In the numerical studies particular emphasis is given to the role played by normal degree-of-freedom in frictional sliding.

UNCLASSIFIED REPORT

ABSTRACT: (U) This document investigates the limiting behavior of a class of one-step M-estimators in heteroscedastic regression models. The mean function is assumed to be known up to parameters, but the variance function is considered an unknown function of a dimensional vector. The variance function is to be estimated nonparametrically by a function of the absolute residuals from the current fit to the mean. Under a variety of conditions when the estimates adapt for scale, i.e., the regression parameter is estimated just as well as if the scale function was known. Connections with the theory of optimal semiparametric estimation are made. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) This report presents the second year accomplishments perfecting the elasto-plastic constitutive equations of Hardin (1978) and their implementation into EPSAP (Elasto-Plastic Soil) Analysis Program). Essential features of soil behavior that result from the soil skeleton being particulate are included in the soil model. It is recognized that plastic behavior of particulate materials depends on direction of effective stress increment as well as state of effective stress. Two classes of stress increment directions are defined with different plastic potential and hardening functions for each class. Work has been directed toward: (1) modeling soil strength in terms of effective stress; (2) modeling work softening behavior for class 1 plastic hardening; (3) modeling class 2 plastic hardening; (4) modeling the class 1 plastic potential function for cyclic loading; (5) possible use of undrained triaxial compression test data for clays; (6) implementation into the finite element program of constitutive models; (7) introduction of two new elements into the analysis program, a modified eight node hexahedron finite element and an eight node infinite element; and (8) improvement of the nonlinear finite element solution strategy.

ABSTRACT. (U) Graded regions of n-(Ga,In)As and p-Ga(As,  
Sb) were incorporated side-by-side as emitter and base  
contacts respectively, into an npn (Al,Ga)As/GaAs  
heterostructure bipolar transistor (HBT). The process  
involved two separate MBE growths, leading to base  
contact regions that were self-aligned to the emitter  
mesas. The devices could be easily probed with pressure  
contacts even prior to any metallization, and excellent  
characteristics were obtained after final metallization.

ABSTRACT: (U) Brain electrical patterns of seven right-handed adults were found to be different preceding accurate and inaccurate performance. Activity overlying the left frontal cortex and the motor and parietal cortices contralateral to the performing hand characterized subsequently accurate left- or right-hand performance. Additionally, strong activity overlying supplementary motor and premotor cortices preceded left-hand performance. Group patterns significantly distinguished subsequently accurate or inaccurate performance by individuals. These measurements suggest that brief, spatially distributed neural activity patterns, or 'preparatory sets', recorded from distinct cognitive, somesthetic-motor, and integrative motor areas of the human brain may be essential precursors of accurate visumotor performance. These precursors of performance accuracy were not present in even highly enhanced conventional averaged evoked potentials. Our findings suggest that important functional relations between areas of the human brain may be characterized by measuring the similarity of wave shape and timing between appropriately preprocessed low-frequency brain waves recorded from different channels at the scalp.

UNCLASSIFIED REPORT

ABSTRACT: (U) Monolithic integration of electronic circuits in silicon has made possible a revolution in electronic computation and signal processing. Today, gallium arsenide integrated circuits (GaAs ICs) are extending this electronic revolution to ever higher speed devices. Optical signal processing, despite its consistent advances and several early successes such as synthetic aperture radar and the optical spectrum analyzer, is falling increasingly behind the electronic competition. Functions which formerly required the speed and parallelism of optics are now being implemented entirely in digital electronics. The reasons for this are several, but one in particular stands out: the lack of emphasis given to compatibility issues between optical and electronic IC fabrication processes. As a result, most integrated optic devices demonstrated to date have been discrete components requiring laborious interfacing to predominantly electronic systems.

## UNCLASSIFIED REPORT

ABSTRACT: (U) Regarding work on the development of  
microstructure during rapid solidification, three areas  
have been addressed. The first of these involved a  
determination of the mechanism of formation of the so-  
called zones A and B in hyper-eutectic Al-transition  
metal alloys. The second area of work involving the  
development of microstructure concerns submerged phase  
transformations. In a study of AL-Be hyper-eutectic  
alloys, it was determined that solidification proceeded  
by a set of phase transformations that may be described  
by a monotectic reaction. The third area of study  
concerning microstructural development involves quasi-  
crystalline AL alloys. In fact, work done in this program  
has concentrated on the potentially beneficial aspects of  
quasi-crystalline phases in the microstructure of AL  
alloys. Work on the consolidation of particulate has  
concentrated on the use of conventional techniques (i.e.  
extrusion) and novel processes (i.e. dynamic compaction).  
An estimate of the mechanical properties of rapidly  
solidified AL alloys has been obtained. As explained  
above, the effect of extrusion is to cause decomposition  
of the rapidly solidified microstructure. A comparison  
has been made, using the alloy AL-8Fe-2Mo, between the  
tensile properties of the decomposed microstructure (i.e.  
extruded) and sub-scale test specimens produced by laser

ABSTRACT: (U) Due to the recent availability of an  
experimental value for the second- and third-order  
electric polarizabilities of the HF molecule, possible  
errors in the previous prediction of these quantities  
have been considered. These include basis sets,  
vibrational corrections, frequency dependence, infinite-  
order correlation corrections, and the effect of triple  
excitations. Despite the inclusion of all of these  
effects, the discrepancy between experiment and theory  
remains. Possible additional corrections are considered  
with emphasis on basis set completeness. Considering the  
difficulty in predicting such sensitive quantities, this  
is rather good agreement. The paper also addresses  
questions of reliability of ab initio calculations for  
such high-order properties as hyperpolarizabilities,  
while identifying some places where the experimental  
results are susceptible to error.

ABSTRACT: (U) An ion beam deposition system was purchased and utilized for research on magnetic materials and devices for high density magnetic information storage. Initial work was carried out on the deposition of permalloy and the deposition of magnetic oxides. The work on permalloy revealed that ion beam deposited materials generally had smaller grain size and lower coercivity than R.F. sputtered materials. It was also found that the grain size and coercivity of ion beam deposited materials increased of a second ion gun were used to bombard the substrate during the deposition process. This work is being continued with support from other sources. The work on magnetic oxides was begun with the deposition of cobalt ferrite. X ray diffraction measurements indicate the material deposited was amorphous and exhibited a hard axis of anisotropy perpendicular to the plane of the film. This work is also being continued with support from other sources.

UNCLASSIFIED REPORT

**ABSTRACT:** (U) In recent years, the group within the National Research Council that oversees our work in the physical sciences became concerned that the nation was not taking full advantage of the potential of the mathematical sciences. Accordingly, the council empaneled a group of outstanding scientists, many of whom, including the panel chairman, Edward David, represent scientific fields that use the results of mathematical research. The panel's task was to assess the adequacy of U.S. resources in support of mathematics. Renewing U.S. Mathematics is the product of that assessment. The panel discovered that recent funding increases in the computer sciences actually mask a downward trend in federal support for mathematics itself. The report lays out a bold remedial program that the panel believes is needed if we are to keep the mathematical sciences in the United States at the world forefront. We should not take for granted the broad practical payoff that derives from advances in pure and applied mathematics. I hope this report will play a part in helping the government, the public, and the scientific community itself to understand the risks we take if we neglect this crucial resource.

ABSTRACT: (U) Work continues on the characterization of the effects of a pitching airfoil on the shear layer structure and growth under open loop forcing. We have shown that locally introduced disturbances can induce significant changes in the growth of the shear layer mixing zone. A separate investigation into the structure of the wake of an oscillating airfoil in a steady, uniform free stream revealed the existence of an axial flow along the cores of the wake vortices. The magnitude of the axial flow appears to depend on both the frequency and amplitude of oscillation.

ABSTRACT: (U) Let  $(U_1, U_2, \dots)$  be a sequence of observed random variables and  $(T_1, (U_1), T_2, (U_1, U_2), \dots)$  be a corresponding sequence of sufficient statistics (a sufficient sequence). Under certain regularity conditions, the sufficient sequence defines the input/output map of a time varying, discrete time nonlinear system. This system provides a recursive way of updating the sufficient statistic as new observations are made. Conditions are provided assuring that such a system evolves in a state space of minimal dimension. Several examples are provided to illustrate how this notion of dimensional minimality is related to other properties of sufficient sequences. The results can be used to verify the form of the minimum dimension (discrete time) nonlinear filter associated with the autoregressive parameter estimation problem.

ABSTRACT: (U) A TEM study of the interphase boundary  
structure of proeutectoid alpha plates in a Ti-7.15% Cr  
alloy has shown that both the broad faces and edges of  
the plates are partially coherent. At the broad faces,  
misfit dislocations are  $1/3 < 1120 >$  whereas at the edges  
they are  $1/3 < 1123 >$ . For normal alpha plates, the  
dislocations are ca. 20nm apart at the broad faces and 8  
nm apart at the edges. At black plates, the low  
temperature morphological variant of proeutectoid alpha,  
the dislocations are ca. 35nm apart. Growth ledges are  
typically 100 - 350 nm apart at the broad faces of  
normal plates and ca. 700 nm apart on black plates. A  
detailed 0-lattice analysis has demonstrated that a  
simple correlation between the misfit dislocation and the  
growth ledge structures does not exist. Growth kinetics  
studies of grain boundary allotriomorphs in Ti-3.9 w/o Co  
and Ti-7.15 w/o Cr have shown for the first time that the  
receptor plate mechanism is operative when the matrix  
phase has a bcc crystal structure. As previously  
predicted, however, this mechanism accelerates growth  
substantially less at a given homologous temperature than  
previous work has shown it to do in fcc matrices. The  
feasibility of detailed fundamental studies of the

ABSTRACT: (U) The crystal chemistry, synthesis, and thermal expansion investigation of NZP-family was completed--in that M superscript12r2P3012 (M superscript1 = Li, Na, K, Rb, Cs), M superscript112r4P6024 = Mg, Ca, Sr, Ba) and a few more compositions were studied. Single crystals of (NZP) and (CZP) were grown, and high-temperature x-ray measurements were made on these crystals to test the validity of a structural model to interpret thermal expansion data. The possibility of the development of a glass-ceramic of NaGe2P3012 was explored. Dielectric measurements made on CaZr4P6024 reveal that in general (NZP)-materials have a low dielectric constant. Three new families, namely diborides (ZrB2, TiB2, and CrB2), Al2O3-GeO2 system and perovskite Pb(Mg1/3Nb2/3)O3 were investigated in order to search for any new low thermal expansion composition, but not much success was achieved in this direction, except that some perovskite compositions displayed low alpha behavior at low temperatures.

ABSTRACT: (U) This research concerns the analysis and synthesis of asynchronous systems that contain discrete-state feedback compensators for continuous state plants. New tools for characterizing both the interfaces and the signals present in these intrinsically hybrid systems were developed. Generalizations of automata theory to real number alphabets were pursued and the application of semigroup theory to the dynamics of such systems has allowed for novel approaches for characterizing the internal state of asynchronous systems to be derived. A simulator for these 'asynchronous machines' has been written and allows us to bridge the gap between ideal systems, on one hand, and systems with physically constrained processing times, on the other.

ABSTRACT: (U) The 2-D correlation/convolution which can be achieved in real time via four wave mixing in nonlinear materials has been investigated in detail to determine the accuracy and signal power investigated in detail to determine the accuracy and signal power possible. This analysis was initiated under other support; the experimental confirmation was completed under this contract. The analysis which is based on Fourier transforms of the equations of non-linear interaction has resulted in a closed form solution for the output and clearly shows how it differs from the desired 2-D correlation. In the example of a scene that is searched for given objects, the accuracy decreases as the ratio of scene to object size increases. The accuracy also resulting in a trade-off between accuracy, size of scanned scene, and power or signal to noise ratio in the output. The analysis was confirmed experimentally in a collinear four wave interaction in the photorefractive material bismuth silicon oxide at 5145 A. The accuracy of the correlation between relatively simple patterns was measured and agreed well with the prediction of the analysis.

## UNCLASSIFIED REPORT

ABSTRACT: (U) Asymptotic simultaneous confidence bands are derived for the survival function under the proportional hazards model of random right-censorship. These bands are based on the maximum likelihood estimator of the survival function, rather than the well-known product limit estimator. In the case where the censoring parameter, denoted by  $\beta$ , is known the bands are asymptotically exact, while when  $\beta$  is unknown the bands are asymptotically conservative. For the case where  $\beta$  is unknown, the proposed bands are shown to be narrower than those proposed by Cheng and Chang (1985). Csorgo and Korvath's (1986) idea of mixing bands is then employed to obtain even narrower bands. As one would expect, under the more structured model, the PLE-based band of Gillespie and Fisher (1979) is shown to be inferior to the MLE-based bands, and this inferiority is more marked as the degree of censoring increases.

ABSTRACT: (U) A summary of the results of the Cerenkov maser development is presented. During the course of this work, operation over the spectral range extending from just below 30 GHz to just above 300 GHz was demonstrated. Sources based upon high-power microwave-tube technology and sources driven by pulse-power generators were both used to drive Cerenkov Masers. In the former type, 10% efficiency from single-pass, untapered resonators were obtained, while in the latter, efficiency was in the 0.1-1% range. Extensive computer codes describing linear and nonlinear aspects of Cerenkov maser operation were also developed.

ABSTRACT: (U) Simultaneous measurements of velocity (in a direction normal to the flame brush) and temperature in premixed, od-stabilized, lean methane/air V-flames demonstrated the presence of high-frequency fluctuations within slowly drifting flame brushes, thus indicating a structure different from that of a simple wrinkled-laminar flame. Both the velocity and the temperature fluctuations gave maximum RMS values at a position somewhere between the unreacted and the product gases. Furthermore, cross-correlation coefficients of these simultaneous signals assumed rather high values within the reaction zone, suggesting the possibility that these fluctuations might be induced by the same governing mechanism (which, according to the theory reported previously, was due to the coupling between chemical kinetics and turbulence). A paper on the genesis of transverse waves in gaseous detonations was published in Combustion and Flame. A manuscript on the thermal structure of turbulent flames was submitted for presentation at the Fall Technical Meeting of the Eastern Section of the Combustion Institute. Another manuscript on turbulence-combustion interactions was in preparation.

ABSTRACT: (U) The main objective of this contract has  
been to find methods of fabricating single-crystal  
nonlinear optical fibers. Successful techniques were to  
be utilized to make crystal fibers useful for nonlinear  
optical devices, particularly devices exploiting second  
order optical nonlinearities. Device concepts and  
applications were also to be formulated. This work was  
initially divided into three parts. The first of these  
emphasized materials purification, characterization, and  
the measurement of physical and chemical properties of  
materials used in the fabrication of single-crystal and  
nonlinear fibers. The second task explored a variety of  
methods of production of single-crystal (SC) fibers,  
recognizing that one method can be applied, even in  
principle, to SC fiber growth of all materials of  
interest. The third task in this program involved the  
measurement of optical properties of the fabricated  
fibers and development of device applications.

ABSTRACT: (U) The principal objective of this experimental investigation of the relationship between flow structure and chemical reaction in turbulent reacting flows is to examine the spatial structure of the unsteady reaction process as it relates to the unsteady velocity field. The configuration studied is a coflowing, non-premixed jet flame. A small perturbation in the fuel jet velocity, produced acoustically, is used to create a very periodic and controllable flame, suitable for conditional sampling. Initial measurements of the unsteady velocity field in the flame have been obtained using laser anemometry. In addition, flow visualization experiments have been conducted using direct and schlieren photography and Mie scattering from seed particles introduced into the flow. Planar laser-induced fluorescence images of the OH radical, which provide spatially and temporally resolved information on the instantaneous location of the reaction zone, have been obtained. A particle tracking technique to facilitate acquisition of velocity field data is being developed.

ABSTRACT: (U) A second-quantized derivation of the quantum (1/f) effect was developed. This derivation is based on the pair correlation function and automatically includes the right form of exchange between fermions and between bosons. Also for the first time a direct calculation of the effect of a finite mean free path was performed. This calculation justifies the calculation of quantum (1/f) noise and results in a correction factor of the order of the unity. As a first step of a more general study of (1/f) in semiconductor devices (n-p) diodes have been investigated with emphasis on (HgCdTe) photodetectors. Quantum (1/f) noise has been calculated in the surface and bulk recombination currents, in the diffusion and field currents, and in the tunneling currents. Due to the large localized electric field at the surface, a larger fractional quantum (1/f) noise power is obtained for surface recombination currents than for similar bulk recombination currents. All quantum (1/f) noise calculations are first principles calculations with no free parameters, based on the quantum (1/f) effect in scattering and recombination cross sections, as well as in tunneling rates.

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper, written for the Proceedings of the First World Congress of the Bernoulli Society of Mathematical Statistics and Probability in Tashkent, 1988, summarizes the most fundamental concepts and relationships in the theory of conditioning in point processes. Though most results are taken from the author's book on Random Measures or from an earlier survey paper, the present emphasis is somewhat different, and there are even a couple of new results, mentioned here without proof. By a point process we mean a random configuration of isolated points in some topological space. Point processes arise naturally in a great variety of contexts, both theoretical and applied.

UNCLASSIFIED REPORT

ABSTRACT: (U) The objective of this study was to acquire  
improved understanding of viscous internal flows related  
to turbomachinery components by analyzing appropriate model  
flow problems. Significant effort was directed towards  
developing basic computational methods which were made  
available to interested researchers involved in  
computational fluid dynamics (CFD) research and to users  
involved in the design of turbomachinery components.  
Several analyses were developed and include an asymptotic  
analysis for the fully developed three-dimensional flow  
in curved ducts, a parabolized Navier-Stokes analysis  
for developing flow in curved ducts, an unsteady Navier-  
Stokes analysis for internal and external flows,  
adaptive grid generation for one and two dimensional  
viscous flows, analysis of the Neumann problem in  
generalized orthogonal coordinates, efficient semi-  
implicit solution techniques consisting of the  
alternating direction implicit multi grid and strongly  
implicit multi grid methods, the direct block Gaussian  
elimination(BGE) method for solution of the Poisson  
equation for the unsteady Navier Stokes analysis of  
incompressible flows. For the flow inside a shear driven  
cavity, the asymptotic flow in curved ducts and clarity  
for interpretation of the available corresponding

UNCLASSIFIED REPORT

ABSTRACT: (U) The basic tenet of fracture mechanics is  
that the stress intensity factor,  $K$ , controls fracture  
and fatigue: here the former claim is critically examined.  
The underlying supporting argument - the original energy  
argument of Griffith and the more modern  $K$ -controlled  
region view - are considered. These considerations  
demonstrate that there are questionable assumptions in  
both, so that the viability of  $K$  as a damage parameter  
for fracture has to be established by the physical  
evidence. The first question then is whether or not the  
critical value of  $K$ ,  $K_{sub Ic}$ , is a material parameter:  
checking data shows it need not be. The second question  
is can the technology be usefully predictive, even in the  
most simple of situations: checking the data shows it to  
be unreliable in this role. At this time then, it remains  
to ask similar questions concerning the role of  $K$  in  
fatigue crack growth and, certainly for the monotonic  
loading case, develop alternatives: these are the  
objectives of the second phase of the program.

UNCLASSIFIED REPORT

ABSTRACT: (U) During the two-year period of this contract, substantial progress was made in the understanding of both the linear and the nonlinear optical properties of direct gap semiconductors and in the implications for high speed, low power, nonlinear optical signal processing. In particular, the detuning and the temperature dependence of the damping of an exciton-polariton was obtained for the first time. The lowest single beam switching energy ( $< 4 \text{ pJ}$ ) and the fastest reported ON/OFF switching ( $< 1 \text{ ns}$ ) bistable device with clearly resolved stable states was demonstrated using the nonlinearity associated with bound excitons in CdS. Thermal effects on the millisecond and microsecond time scales were experimentally studied. Optical bistability due to induced absorption near the free and bound exciton was experimentally studied with and without a Fabry-Perot cavity. Large degenerate four-wave mixing signals were observed near free and bound excitons in CdS at cryogenic temperatures. Nonlinear transmission signals were studied at different detunings below the free exciton resonance and at temperatures up to 120 K. These signals were interpreted in terms of a broadening of the free exciton resonance by exciton-exciton collisions. The quantum confined stark shifting of a quantum dot was performed for the first time. A new

ABSTRACT: (U) Since its establishment in 1972, research at the Center for Mathematical System Theory has generated over 100 published papers. At the same time, the Center has served as a focal point for a considerable part of the system-theoretic research in the U.S. and elsewhere, through an active visitor program and through recruitment of outstanding doctoral students. This is especially true for the development and application of advanced algebraic and algebraic-geometric techniques in the system-theoretic context. The Center is an interdisciplinary, interdepartmental group, a basic function of which is to provide coordination and collaboration between advanced mathematics and engineering.

ABSTRACT: (U) To help provide a better understanding of the temperature dependence of the kinetics of diatomic metal radical oxidation reactions, experimental measurements were made in the 450 to 1750 K temperature regime. An HTFR (high-temperature fast-flow reactor) was used. The metal radical concentrations were measured by laser-induced fluorescence. The general uses of this spectroscopic technique for rate measurements on reactants and products, as well as for product species identification and product state determination, are reviewed. The radicals studied in the HTFR on this grant are  $\text{AlO}$ ,  $\text{AlCl}$  and  $\text{BCl}$ . Production methods for these are discussed. For the reaction  $\text{AlO} + \text{CO}$  yields  $\text{AlO}_2 + \text{AlO} + \text{CO}$  we obtain  $k(T) = 2.5 \times 10^{-10}$  to the minus 14th power  $\exp(400/T)$  cc/molecules/s. This negative activation energy implies  $D(\text{O-AlO}) > D(\text{O-CO}) = 530$  kJ/mol, which is in apparent disagreement with the  $\text{OAlO}$  dissociation energy obtained for  $\text{AlO}_2$  from  $\text{Al}_2\text{O}_3$  evaporation-mass spectrometry studies. It is argued that the latter  $\text{AlO}_2$  may have a different structure from that of the present work. For the reaction between  $\text{AlCl}$  and  $\text{O}_2$  we find  $k(T) = 8.8 \times 10^{-10}$  to the minus 13th power  $\exp(-2990/T) + 1.5 \times 10^{-10}$  to the minus 10th power  $\exp(-10800/T)$  cc/mol/s, which is compatible with a mechanism where the  $\text{AlO}_2 + \text{Cl}$  product channel dominates at lower temperatures, while the  $\text{OAlCl} + \text{O}$  channel dominates at higher temperatures. The  $\ln k(T)$  versus dependence of the  $\text{AlCl}/$

ABSTRACT: (U) Research on optical data processing for missile guidance and robotics is described. Our major emphasis is pattern recognition using feature extraction (Fourier coefficients, moments and chord features) and correlation (using distortion-invariant synthetic discriminant function matched spatial filters). All research in pattern recognition concerns multi-class distortion-invariant pattern recognition. Recent research includes: different feature extraction post-processors, new algorithms to extract distortion parameters from chord features and a hierarchical moment feature processor for distortion parameter estimation. Extensive database tests of moments and synthetic discriminant functions have been performed. Component research has addressed AO cells with performance measures and detector effects described. Matrix-vector research includes: error source analysis, a new quadratic matrix algorithm, and initial laboratory system results with attention to the electronic support system and the laboratory system fabrication. ABSTRACT: (U) Laser induced processes on conventional and phase conjugated surfaces are investigated theoretically. Resonance fluorescence of two level atoms on smooth and rough surfaces are reviewed. The new phenomenon of a radiative dipole at a phase conjugated surface (PCS) is examined, where the lifetime of the dipole is virtually infinite under certain conditions. PCS originates from the interference of two laser beams incident on an absorbing layer and is discussed in terms of a phenomenological model and a hydrodynamic theory, where laser-induced periodic structure and the PCS reflectivity are analyzed. Finally, practical applications of these new phenomena occurring on PCS are discussed.

ABSTRACT: (U) A simple problem involving the identification of an explosive source as being unburied or buried using a pattern recognition based analysis of buried ground accelerometer measurements is presented. This problem illustrates the advantages of computerized information extraction from the measured waveforms. Information was extracted from the frequency and cepstrum descriptions of the waveforms in addition to the more traditional time domain information. These signal features were incorporated into a Fisher's Linear Discriminant pattern recognition procedure. Previously unseen signals were classified with up to 100% accuracy depending on which features were used. Close in explosive source measurements present unique problems to a pattern recognition based analysis approach. These problems are reviewed and approaches illustrated.

ABSTRACT: (U) AIn analytical model was formulated for the calculation of unsymmetrical pressure distributions inside the cavities of a multi-stage labyrinth seal. The model is based on a set of linearized continuity and momentum equations for the throughflow, and can account for the effects of rotation, whirl, flow swirl, differential gap width and (limited) compressibility. Preliminary calculations show excellent agreement with non-whirling side-force data in the literature. Also, models are being constructed that will permit calculation of the effect of these seal forces on the running stability of flexible, highly loaded turbomachines, with the Space Shuttle Main Engine serving as the prototype of such machines.

ABSTRACT: (U) Low-frequency acoustic microscopy has demonstrated a tremendous potential for the nondestructive evaluation of metals, composite materials, and structural ceramics. This proposal allowed us to build a new, improved instrument with which can make not only amplitude, but also phase, measurements. The addition of the phase measurement capability allows us to do two dimensional image processing to extract more information from our measurements than is presently done with amplitude only acoustic microscopes. Also, the addition of the phase measurement capability allows us to measure profiles of samples with great accuracies.

ABSTRACT: (U) This research envisages development of constitutive models for joints in rock (concrete) subjected to cyclic loads. The objective is to implement the models in (numerical) solutions of boundary value problems involving solids and joints subjected to dynamic loads such as blasts and earthquake. Hence, it is appropriate to develop models for both the joints and the intact or solid (concrete) media in which the joints occurs. This report contains description of a new hierarchical plasticity-based constitutive model, laboratory testing using a multiaxial device and verification for the intact concrete used in the investigation.

## UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Doctoral thesis.

ABSTRACT: (U) A study was made to integrate finite element-based-optimal structural design methods and computer-science methods into a computer-based system containing a database, a program library and machine communication link. Emphasis is placed upon database management concepts for structural design. Important components required to build a computer-aided structural design system are described. A number of database management concepts -- hierarchical, network and relational data models, conceptual, internal and external view of data organization, normalization of data, and global and local database are discussed with reference to structural design data. A methodology to design a database is proposed. Three levels of data organization-conceptual, internal and external are suggested. A methodology to construct a numerical data model is described. This model supports data of various types of large matrices such as banded, skyline and hypermatrices. Requirements of database management system and components needed to develop it are discussed. Language requirements to enable good communication link between designer and computer are formulated. A database

UNCLASSIFIED REPORT

ABSTRACT: (U) The need for a micromechanical approach to modeling the stress-strain response of granular soil is discussed and justified. The report focuses on the small shear strain ( $\gamma < \text{or} = 0.01\%$ ) behavior, and investigates the validity of analytically modeling uniform, rounded-grained quartz sands by arrays of identical elastic quartz spheres. First the stress-strain properties of 8 regular arrays of spheres are studied, focusing on isotropic and transversely isotropic boundary loading. An analytical procedure is established for determining the elastic moduli of a random assemblage of equal elastic spheres of arbitrary mean porosity, subjected to isotropic confining pressure. The procedure uses the properties of the regular arrays already described, and calculates the macroscopic moduli through the self consistent method. The procedure was applied to compute the shear and bulk moduli of assemblages of quartz spheres which were then compared with static and dynamic measurements on quartz sands from the literature. The theoretical sands are significantly stiffer than actual soils due to the lower number of effective

contacts in actual sands. However, excellent agreement was found with resonant column shear modulus measurements on Ottawa sand, after subjecting it to a large number of cycles of shear prestraining which increased the number of contacts toward the theoretical value.

ABSTRACT: (U) A program involving the investigation and characterization of reactions of coordinatively unsaturated organometallic species is described. The program emphasizes the measurement of rates of reaction of photolytically produced coordinatively unsaturated species with the parent and rates for cluster formation. Experimental measurements are performed using a time resolved transient absorption apparatus which uses a line tunable CO laser to record spectral and kinetic information by means of probing absorptions in the CO stretch region of the infrared. Systems that have been investigated include coordinatively unsaturated species generated from the Fe(CO)5, Cr(CO)6 and Mn2(CO)10 parents. The results of experiments with these systems are briefly discussed.

UNCLASSIFIED REPORT

ABSTRACT: (U) The origins of the unpredicted satellite  
lines about the central resonance of the CARS spectrum  
found in a previous study have been explored. The  
objectives of the program were to determine the  
dependence of the line structure on the input laser  
intensities and on tuning of the the resonant frequency.  
In the previous AFOSR-supported study, electronically  
resonant coherent anti-Stokes Raman spectroscopy (CARS)  
of OH was demonstrated for the first time using a flame  
source. Theory and experiment were in generally good  
agreement, except for the presence of satellite lines  
(extra resonances) about the strong central component. In  
order to investigate reliably the power dependence of the  
resonance CARS spectrum and thereby test for saturation  
effects, a single mode, pulsed, tunable dye laser was  
utilized to insure selective excitation of a single  
resonance. The resultant spectra show clearly that  
saturation occurs at input laser pulse energies of the  
resonant frequency of about 0.1 millijoules. Saturation  
effects are particularly apparent when the CARS pump  
frequency is on line center of the selected electronic  
transition. Tuning away from line center and/or reducing  
input pulse energy produces a notable decrease in the  
strength of the satellite lines relative to the central

UNCLASSIFIED REPORT

ABSTRACT: (U) The major findings from a comprehensive study on the role of microstructure on the susceptibility to environmental embrittlement of high strength aluminum alloys are presented and discussed. Most of the studies used commercial 7075, or a high purity equiaxed version, H7075, or a similar powder version 7090. Through the innovative use of loading mode and straining electrode test, stress corrosion cracking was shown to be controlled by the introduction and internal distribution of hydrogen, particularly to grain boundaries. This was the case for the underaged and peak aged microstructures, with the latter being the most susceptible. The SCC behavior of the even more resistant overaged microstructure was shown to be controlled by anodic dissolution processes, predominantly associated with slip bands. Aluminum alloys were also shown to be susceptible to embrittlement under conditions of cathodic polarization correcting a widely held belief that concomitant anodic processes are required. Studies using controlled microstructures were able to rank the importance of different microstructural features to help develop alloy design strategies for more environmentally

resistant alloys--the most effective features are those grain interior precipitates which promote fine, homogeneous slip either by reduced particle cutting or enhanced dislocation generation; fine, grain boundary precipitate free zones were found not to be very important, except in their role in reducing the local strength of the boundary region.

ABSTRACT: (U) This report describes the current status of a research project whose aim is to develop a hydrostatic bearing, for rotating machinery, whose dynamic characteristics may be tuned during operation of the machine. The purpose of this is to enable the operator to exercise some control over machine critical speeds and vibrations. A computer program has been written which will predict both the static and dynamic characteristics of a hydrostatic bearing. The program allows for the presence of accumulators linked to the hydrostatic bearing recesses via flow restrictors. Output from the computer program has been used as input data to a second computer program which calculates machine vibration amplitude variation with running speed. Theoretical machine characteristics obtained in this way have been used to aid the design of a test rig which will be used to examine the practical performance of the new bearing type being developed.

ABSTRACT: (U) A cascade lattice parameter filter for multidimensional signals is presented. It inherits the orthogonality property of the Gray Markel normalized lattice, which makes for improved numerical robustness, as well as the structural stability property, which means that the filter is stable for every choice of parameters that satisfies the constraint of orthogonality. An implementation of the lattice sections is presented which has multiple inputs and outputs, as networks of elementary  $(2 \times 2)$  orthogonal rotations. Our analysis establishes a fundamental connection between structural stability and the notions of passivity and losslessness. In fact, we show that for a broad family of orthogonal cascade filters structural stability is achieved if, and only if, the filter has passive terminations.

UNCLASSIFIED REPORT

ABSTRACT: (U) The fundamental scientific issues impeding the integration of laser diffraction particle sizing techniques into intelligent sensors for next generation propulsion systems have been identified. This research contributes to the knowledge base necessary to significantly advance the laser diffraction concept. The research addresses three areas, inverse scattering algorithms, multiple scattering, and the problems of laser beam deflections due to refractive index gradients in hostile propulsion environments. Progress has been made in the development of direct integral transform techniques for the inverse problem which potentially can operate at frequencies on the order of 10 kHz as needed for propulsion system sensors. Adequate inversion performance on bimodal distributions with signal to noise ratios as low as 10% has been demonstrated. The multiple scattering problem has been formulated as a matrix operation, and a corresponding scheme for the inversion of diffraction data under multiple scattering conditions has been proposed. A prototype computer generated hologram which generates a hollow cone of scattered light has been fabricated. Experiments are underway to demonstrate the usefulness of this development to the inverse multiple scattering problem.

ABSTRACT: (U) We have made progress in a variety of areas within this program since our original report of DFWM in a thin film waveguide. That original experiment utilized liquid carbon disulphide (CS<sub>2</sub>) as the nonlinear mixing medium in the form of a cladding on a planar sputtered 7059 glass waveguide. A number of obvious deficiencies exist in configuration: (a) the physical form of the nonlinear medium (ie a liquid is not very practical), (b) the optical field strength in the nonlinear medium is small since only the evanescent tails of the guided mode exist in the nonlinear cladding, and (c) the magnitude of the nonlinear index in CS<sub>2</sub> is approx. 10 to the minus 18th power per sq m per v is not particularly high. To improve upon these deficiencies what is required is a nonlinear material preferable in a practical solid form which can be formed into low loss optical waveguides. Semiconductor doped glasses were identified as an excellent candidate material to meet these requirements. This is a glass host containing mixtures of CdS and CdSe compounds semiconductor crystallites.

## UNCLASSIFIED REPORT

ABSTRACT: (U) The infrared laser excitation of the internal vibrational mode of a diatomic molecule adsorbed on a metal by electron hole excitations. Simple expressions for the populations of the vibrational levels, the mean number of vibrational quanta and the rate of energy transfer between the infrared laser and the metal surface at the steady state are derived. an equation of evolution can readily be solved numerically to determine the time necessary to reach this steady state. The criteria of applicability of the Markov approximation (which leads to the golden rule) is clearly established, where it is seen that this approximation may not be used to compute the evolution of the populations of the vibrational levels. The random phase approximation is shown to give the correct kinetic equation for the populations of the vibrational levels. The excitation of carbon monoxide adsorbed on a copper surface is analyzed quantitatively.

ABSTRACT: (U) This report investigate methods for obtaining diffraction limited images of space objects, despite the turbulent atmosphere, by reconstructing images from data provided by optical interferometers (particularly stellar speckle interferometry). Major accomplishments include the following: (1) A new closed form recursive algorithm was invented for reconstructing sampled objects having latent reference points. (2) Improvements in the iterative Fourier transform algorithm were devised, solving the stagnation problems of stripes and of simultaneous twin images. (3) Uniqueness of the reconstructed image was demonstrated empirically. (4) Reconstruction of complex valued objects was shown to be possible. (5) The Hayes Quatieri recursive algorithm was shown to suffer from a uniqueness problem, and that algorithm was generalized. (6) An improved method for estimating the object's Fourier modulus from stellar speckle interferometry data was devised.
